## PREFACE

Population projections are widely used today in social and economic planning and policy decisions. Responding to the growing demand from public and private users for increasingly sophisticated population projections, Statistics Canada is continuously engaged in the conduct of projections-oriented research, the development of data base and the technical capabilities. This report, which is the outcome of these efforts, presents the first official Statistics Canada population projections by age and sex for Canada, provinces and territories for each year from 1972 to 2001.

These projections are, of course, not predictions; they reflect the future growth trends, the emerging age-sex structure and the population distribution across the country **under the stated assumptions**. Four alternative sets of projections are included in this report to cover the plausible range of the factors governing future population growth. In addition, some special purpose projections are included to aid demographic analysis and policy studies. Recognizing, however, the uncertainties of the factors affecting especially the level and pattern of future fertility or migration, Statistics Canada will follow a policy of revising these projections regularly every three years or, if necessary, more frequently depending on the actual demographic changes.

In the preparation of these projections, several persons in the federal and provincial governments as well as the universities were consulted on the various background papers containing methodology and assumptions regarding future mortality, fertility and migration. While acknowledging their assistance, none of these individuals nor departments is held responsible for these projections. Final assumptions were arrived at by a team including K.S. Gnanasekaran, J. Perreault, A. Romanuc and D. Vanasse-Duhamel who jointly developed the Statistics Canada Population Projections Model (SCPM) and prepared this report for publication with the help of the staff of the Population Estimates and Projections Division, Census Field.

## PRÉFACE

De nos jours, les décisions en matière de politique et de planification économiques et sociales tiennent compte dans une large mesure des projections de population. Afin de répondre aux exigences croissantes des secteurs privés et publics, Statistique Canada a mis sur pied un programme permanent de recherches sur les projections, tant sur le plan de l'amélioration des données de base que de la méthodologie. La présente étude, née de ces efforts, présente les premières projections démographiques officielles publiées par Statistique Canada; ces projections ont été établies pour le Canada, les provinces et les territoires, par année depuis 1972 jusqu'à 2001, selon l'âge et le sexe.

Ces projections ne constituent évidemment pas des prédictions; elles reflètent seulement l'évolution future de la croissance démographique, de la structure selon l'âge et le sexe et de la répartition géographique de la population **en fonction des hypothèses énoncées**. Les quatre projections incluses dans ce rapport sont censées couvrir l'éventail des possibilités de croissance de la population dans l'avenir. On a également ajouté certaines projections dans le but de faciliter l'analyse des résultats et de permettre l'élaboration de diverses politiques. Étant donné la part d'incertitude liée aux facteurs déterminant le niveau et la structure de la fécondité et de la migration futures, Statistique Canada a décidé de réviser ces projections tous les trois ans, et même plus souvent, si cela s'avérait nécessaire, à la lumière de l'évolution ultérieure.

Lors de la préparation de ces projections, on a consulté plusieurs personnes appartenant aux administrations fédérale et provinciales ainsi qu'aux universités, dans le but d'obtenir leur avis au sujet de la méthodologie et des hypothèses retenues quant à l'évolution de la mortalité de la fécondité et des migrations. Tout en étant reconnaissants à ces personnes de leur collaboration à cette étude nous en assumons l'entièbre responsabilité. Le choix définitif des hypothèses a été fait par une équipe formée de K.S. Gnanasekaran, J. Perreault, A. Romanuc et D. Vanasse-Duhamel, qui ont travaillé ensemble à l'élaboration du modèle de projection de population de Statistique Canada et ont préparé cette étude en vue de sa publication avec l'aide du personnel de la Division des estimations et projections démographiques, Secteur du recensement.

## CHAPTER 1

### Introduction

In an endeavour to meet various requirements of governments, industry and business, and to promote public awareness of the potential of population growth in Canada, Statistics Canada is continuously engaged in the study of current demographic trends and in the development of population projections. This set of projections is the first to be released as an official Statistics Canada publication. A previous attempt to project Canada's population dates back to 1969, and that set was released as a mimeographed document.<sup>1</sup>

The present set of projections differs in two major ways from the earlier one. First, whereas the 1969 projections were limited to Canada only, the present set pertains to Canada and the provinces. Although provinces occasionally produce their own population projections, Statistics Canada's decision to issue its projections by provincial breakdowns was taken in response to numerous requests from government and private users for projections by provinces which would be tied to the national projections, and which, as such, would be comparable with reference to both the format of the output and to the underlying methodology and data base.

Second, the two sets of projections differ with regard to the period they cover. Whereas the earlier projections were of a medium range covering the period 1969 to 1984, the present set is extended to the year 2001, and as such can be regarded as long-term projections. For most purposes for which population projections are used, medium range projections are considered to be adequate. However, there are many cases where long-term projections are needed, such as instances in which solutions are sought to problems associated with urban development and the evolution of ecosystems in a highly industrialized setting. Long-term planning in such areas as energy resources, housing, transportation and public utilities requires long-term population projections. The full impact that changes in mortality, migration or fertility are ultimately going to exert on the size and age structure of a population, cannot be adequately measured unless the period of time covered by projections is long enough. For this reason, long-term projections are also useful as an aid in the formulation of population policies.

In preparing these projections no attempt was made to predict Canada's future population, and consequently users should not view them as a prediction of the future population size and structure of Canada and the provinces. Nor should they be regarded

## CHAPITRE 1

### Introduction

Pour tenter de répondre aux divers besoins des gouvernements, de l'industrie et du commerce, et afin de renseigner le public sur le potentiel de croissance de la population canadienne, Statistique Canada a mis sur pied un programme permanent d'analyse des tendances démographiques récentes et de projections démographiques. Ces projections sont les premières à paraître dans une publication officielle de Statistique Canada. Les projections précédentes, qui ont paru sous forme de document polycopié<sup>1</sup>, remontent à 1969.

Les présentes projections diffèrent des précédentes sous deux aspects principaux. Premièrement, les projections de 1969 se limitaient au Canada, alors que celles-ci portent sur le Canada et les provinces. Quoique les provinces établissent parfois leurs propres projections, Statistique Canada a décidé de publier des projections par province afin de répondre aux nombreuses demandes, de la part des secteurs gouvernementaux et privés, de projections par province étroitement liées aux projections nationales et de ce fait, comparables quant au choix des données de base, de la méthodologie et de la présentation des résultats.

En second lieu, ces projections diffèrent en ce qui concerne la période visée. Les projections précédentes avaient une portée moyenne et couvraient la période 1969-1984, tandis que celles-ci vont jusqu'à l'an 2001, et à ce point de vue, elles constituent des projections à long terme. Dans la plupart des cas les projections de portée moyenne sont suffisantes. Toutefois, il arrive souvent que des projections à long terme soient nécessaires, par exemple lorsqu'il faut trouver des solutions aux problèmes liés au développement urbain et à l'évolution des écosystèmes dans une société fortement industrialisée. La planification à long terme dans des secteurs comme les ressources énergétiques, le logement, les transports et les services publics, requiert des projections démographiques à long terme. L'ensemble des répercussions qu'auront finalement sur l'effectif et la composition selon l'âge d'une population, l'évolution de la mortalité, de la migration ou de la fécondité, ne peuvent être mesurées de façon convenable que si la période de projection est suffisamment longue. Pour cette raison, les projections à long terme servent également à l'élaboration de politiques de population.

Il importe de souligner certains aspects des projections présentées dans ce rapport. Nous ne prétendons pas prédir la population future du Canada; les utilisateurs ne devraient donc pas voir dans ces projections une prédition de l'effectif et de la composition futurs de la popula-

<sup>1</sup> "The Population Projections for Canada, 1969-84", *Analytical and Technical Memorandum No. 4* (Ottawa: Dominion Bureau of Statistics, April 1970).

<sup>1</sup> "The Population Projections for Canada, 1969-84", *Analytical and Technical Memorandum No. 4*, Bureau fédéral de la statistique, Ottawa, avril 1970.

as a simulation exercise undertaken to display paths of population growth under a variety of conditions which are set without any explicit or implicit assumptions as to the likelihood of their future occurrence. The assumptions underlying these projections are based on a careful analysis of trends in the components of population change — mortality, fertility and migration — and as such can be viewed as the most plausible ones, reflecting the likely future movement of these components.

The projections presented here are "conditional" projections, in that the projected future size and age structure of the population will be attained if demographic trends during the projection period coincide with those implied in the underlying assumptions. As such, they provide a useful insight into potential future changes in the growth, structure and spatial distribution of Canada's population. Despite all the efforts which have been made to obtain plausible assumptions about future patterns in the components of population change, there remain considerable uncertainties about the actual levels which they will ultimately attain, and consequently users are offered alternative projections, thus enabling them to make contingency plans to account for these uncertainties.

This report is composed of three major parts. The first part is devoted to the statement of the assumptions underlying the projections. The main trends and features which emerge from the analysis of the projection results are presented in the second part. In an endeavour to ensure that users would have access to the projections for their diverse requirements as soon as possible, no attempt was made to present a detailed analysis of the projection results. However, considerable space has been devoted to describe the assumptions utilized and the underlying methods and rationales. In doing so, it is felt that the user will be given all relevant information to help him to become aware of the strengths and weaknesses of the projections series he selects as the most reasonable ones for his particular needs.

Part three consists of the detailed tables containing alternative projections series for the 1972-2001 period on population by sex and five-year age groups for Canada and the provinces. These are series that have been selected as those most likely to encompass the future population size and structure of Canada. It also contains a few special purpose projections. Other unpublished projections series are listed in the Appendix and can be obtained upon request for the cost of computer time, xeroxing and clerical support by writing to Dr. K.S. Gnanasekaran, Population Estimates and Projections Division, Census Field, Statistics Canada, Ottawa K1A 0T7.

tion du Canada et des provinces. On ne doit pas non plus les considérer comme un simple exercice de simulation dont le but serait de présenter les directions de la croissance démographique en fonction de diverses conditions déterminées sans faire d'hypothèse explicite ou implicite quant à leur vraisemblance. Les hypothèses sur lesquelles sont fondées ces projections ne sont nullement choisies d'une manière arbitraire; elles reposent sur une analyse approfondie des facteurs du mouvement de la population: mortalité, fécondité et migration. De ce fait, elles peuvent être considérées comme les hypothèses les plus plausibles de l'évolution future de ces trois facteurs.

Les projections présentées ici sont "conditionnelles" en ce sens que la structure et les effectifs prévus se réaliseront seulement si les conditions démographiques qui prévaudront au cours de la période de projection coïncident avec celles avancées dans les hypothèses. Comme tel, ces projections permettent d'apercevoir l'évolution éventuelle de l'effectif, de la structure et de la répartition géographique de la population du Canada. En dépit des efforts déployés pour établir des hypothèses vraisemblables, on ne peut déterminer avec certitude laquelle se réalisera finalement. Par conséquent, nous offrons aux utilisateurs plusieurs projections afin qu'ils puissent tenir compte des impondérables liés à tout exercice de ce genre.

Ce rapport est divisé en trois grandes parties. La première est consacrée à l'énoncé des hypothèses sur lesquelles sont fondées les projections. Les tendances et les caractéristiques principales qui ressortent de l'analyse des résultats sont présentées dans la deuxième partie. Afin de rendre ces projections accessibles le plus tôt possible, nous n'avons pas tenté de présenter une analyse détaillée des résultats. Par ailleurs, une bonne part du texte est consacrée à la description des méthodes et à la justification des hypothèses de base. De cette façon, croyons-nous, l'utilisateur sera en mesure de choisir les projections les plus adaptées à ses besoins particuliers.

La troisième partie contient les tableaux détaillés des projections de la population du Canada et des provinces pour la période 1972-2001, répartie selon le sexe et par groupe d'âges. Ces projections ont été jugées les plus susceptibles de cerner la composition et l'effectif futurs de la population du Canada. Cette partie contient également quelques projections établies pour répondre à des besoins particuliers. D'autres projections non publiées sont énumérées dans l'appendice et peuvent être obtenues sur demande; leur prix dépendra des coûts respectifs de temps-machine, de la photocopie et du travail de bureau. **PARTIE I**  
MÉTHODOLOGIE ET HYPOTHÈSES

## CHAPTER 2

### General Methodology

The methodology used to produce population projections presented in this report is based on the **component** approach. According to this approach, each component of population change – mortality, fertility and migration (external and internal) – was projected separately in the form of appropriate rates and ratios which were then applied to the base population to generate future population by sex and age.<sup>1</sup>

Furthermore, the component method was utilized to generate projections for each province and the Yukon and Northwest Territories separately, and these were then aggregated to obtain the national population projections.

The specific methods used to project the three components of population change – mortality, fertility and migration – are described in Chapters 3, 4 and 5. These chapters also provide an analysis of the patterns of provincial differentials which were utilized in the formulation of mortality, fertility and migration assumptions. Consequently, the general approach adopted for these projections is referred to in this report as the **regional component method**.<sup>2</sup>

It should also be pointed out that the regional component method was programmed in great detail to yield projections by sex and single years of age for each province and territory. The present projections are based on the post-censal population estimates of June 1, 1972, and are made for each year through 1986. Moreover, these projections were extended for the period 1986-2001 on the assumption that the demographic parameters would remain constant at the levels projected to the end of the first projection period (i.e., 1986). The long-term projections to the year 2001 were done to comply with the demand for such projections in long-term planning. However, it must be emphasized here that the thrust of our work relates primarily to the period 1972-1986.

<sup>1</sup> Detailed technical papers describing the projections of fertility, mortality and migration, as well as the algorithm used for population projections, are forthcoming as separate publications.

## CHAPITRE 2

### Méthodologie générale

La méthodologie suivie dans la présente étude est fondée sur la méthode des **composantes**. C'est-à-dire qu'on a projeté individuellement chaque composante de l'évolution démographique (mortalité, fécondité, migrations interne et externe) sous forme de rapports et de taux appropriés qu'on a appliqués à la population de départ afin de déterminer la population future selon le sexe et l'âge<sup>1</sup>.

La méthode des composantes a servi à établir les projections de chaque province, du Yukon et des Territoires du Nord-Ouest, individuellement, lesquelles ont ensuite été groupées pour former les projections de la population du Canada.

Les méthodes spécifiques utilisées pour projeter les trois composantes de l'évolution de la population (mortalité, fécondité et migration) sont décrites de façon détaillée aux chapitres 3, 4 et 5. On y trouvera également une analyse de la position des provinces par rapport à celle du Canada sur laquelle reposent les hypothèses. C'est pourquoi on parlera de la **méthode des composantes régionales**<sup>2</sup> pour désigner la méthode générale adoptée pour ces projections.

Il convient également de souligner que la méthode des composantes régionales a été conçue de façon à fournir des projections détaillées selon le sexe et par année d'âge pour chaque province et territoire. Comme population de départ nous utilisons les estimations de population au 1er juin 1972. Établies pour chaque année jusqu'à 1986, ces projections ont été prolongées pour inclure la période 1986-2001, en maintenant les hypothèses constantes au niveau prévu pour 1986, fin de la première période de projection. Les projections à long terme, qui vont jusqu'à l'an 2001, ont été établies pour répondre à la demande de projections de ce genre dans le cadre de la planification à long terme. Il faut souligner toutefois que le plus gros de nos efforts a porté sur la période allant de 1972 à 1986.

<sup>1</sup> Des études détaillées décrivant les projections de fécondité, de mortalité et de migration, ainsi que l'algorithme de projection paraîtront dans des publications distinctes.

<sup>2</sup> K.S. Gnanasekaran et A. Romanuk, *DBS Population Projections for Canada based on the 1971 Census Data: A Regional Approach*, Bureau fédéral de la statistique (recensement), mars 1971, page 20 (Étude préliminaire).

## CHAPTER 3

### Mortality Projection

The crude death rate of Canada was 7.3 per thousand population in 1971. The most recent official life table for Canada reported an expectation of life at birth of 68.8 years for males and 75.2 years for females in 1966. Calculations for the period 1968-1970 showed a life expectancy of 69.2 years for males and 76.1 years for females, implying that mortality reduction still continues in Canada. Another important aspect of past trends has been the widening gap between the average life span of men and women. In 1930-1932, the difference was two years, but since then the difference has gradually increased to more than six years as shown in Table 3.1.

From the standpoint of projections, therefore, two questions arise: (a) Will the expectation of life at birth continue to increase, and if so, by how much will it increase over the projection period? (b) Will the gap between the sexes widen further or begin to converge at some future date? Although no answer to these questions can be conclusively given at this time, some indications with regard to the future course may be obtained by comparing the historical experiences of countries that are ahead in this field, e.g., Sweden, Norway and the Netherlands. Canada ranks among the top ten low mortality countries in the world and its position of sixth rank suggests that there is possible scope for further gains in the expectation of life at birth.<sup>1</sup>

In 1968, Norway had the highest expectation of life at birth for females at 76.9 years which is 0.8 years longer than that obtained in Canada. For males, the highest life expectancy was observed in Sweden, 71.8 years, and this is 2.6 years more than that for males in Canada. With regard to the mortality differentials by sex, the initial gap was not narrowed in any of these countries; on the contrary, it continued to widen gradually as it did in Canada. In this setting, it would seem reasonable to assume further reduction in mortality in Canada and a continuation of the gap between the two sexes.

The foregoing trends and differentials in mortality which emerged over time are the result of a great number of factors – biological, medical, demographic and socio-economic. These are not always fully understood, and sometimes, are difficult and even impossible to grasp despite their significance in inferring the future course of mortality. Besides the sex

<sup>1</sup> The rank order is based on the level of expectation of life at birth for females in 1968. See K.S. Gnanasekaran, *Mortality Trends and Projections by Causes of Death in Canada, 1950-1990*, Harvard Actuarial Conference, Boston, 1973, p. 6.

## CHAPITRE 3

### Projection de la mortalité

Le taux brut de mortalité au Canada était de 7.3 pour 1,000 habitants en 1971. La plus récente table officielle de mortalité au Canada indiquait, en 1966, une espérance de vie à la naissance de 68.8 ans chez les hommes et de 75.2 ans chez les femmes. Nos calculs pour la période de 1968 à 1970 donnent une espérance de vie de 69.2 ans chez les hommes et de 76.1 ans chez les femmes, ce qui signifie que la mortalité continue à baisser au Canada. Un autre aspect important qui se dégage des tendances antérieures est l'élargissement de l'écart entre la longévité moyenne des hommes et des femmes. En 1930-1932, l'écart était de deux ans, mais depuis il s'est progressivement élargi et il est maintenant de plus de six ans (voir tableau 3.1).

Du point de vue des projections, deux questions se posent: a) l'espérance de vie à la naissance continuera-t-elle à augmenter, et dans l'affirmative, quel en sera l'accroissement au cours de la période de projection? b) l'écart de longévité entre les hommes et les femmes continuera-t-il à s'élargir ou commencera-t-il à se réduire dans un avenir prochain? Bien qu'on ne puisse pour l'instant répondre de façon définitive à ces questions, on peut faire certaines suppositions quant à l'avenir en observant l'évolution historique des pays qui sont en avance dans ce domaine, par exemple, la Suède, la Norvège et les Pays-Bas. Le Canada se classe parmi les dix pays du monde où la mortalité est la plus faible et sa position, au sixième rang, permet de présager un nouvel allongement de l'espérance de vie<sup>1</sup>.

En 1968, c'est en Norvège que l'espérance de vie à la naissance était la plus élevée chez les femmes avec 76.9 ans, soit 0.8 an de plus qu'au Canada. Chez les hommes, l'espérance de vie la plus longue avait été observée en Suède où elle était de 71.8 ans, soit 2.6 ans de plus qu'au Canada. En ce qui concerne la surmortalité masculine, l'écart observé au départ ne s'est resserré dans aucun de ces pays; au contraire, il a continué à s'élargir progressivement, comme au Canada. Dans cette perspective, on peut raisonnablement supposer une poursuite de la baisse de mortalité au Canada et le maintien de l'écart entre hommes et femmes.

Cette orientation de la mortalité observée au cours des années s'explique par l'intervention d'un grand nombre de facteurs: biologiques, médicaux, démographiques et socio-économiques. Ces facteurs ne sont pas toujours totalement compris, et parfois, il est difficile voire même impossible de les saisir malgré toute l'importance du rôle qu'ils jouent dans l'évolution de la mortalité. Outre le

<sup>1</sup> Le rang est fondé sur le niveau d'espérance de vie à la naissance chez les femmes en 1968. Consulter le document de K.S. Gnanasekaran intitulé: *Mortality Trends and Projections by Causes of Death in Canada, Harvard Actuarial Conference, Boston, 1973*, page 6.

variable, some of the more salient factors affecting mortality changes are age and causes of death. Among the non-demographic factors whose influences are not easy to assess, the most important are medical progress, hospital facilities, and health insurance. Consequently, the tempo and pattern of the expected future decline in mortality in Canada are inferred here by examining past trends in terms of the three parameters of age, sex and causes of death. It is hoped that the analysis by causes of death will reflect to a large extent the effects of past trends in medical advances in the country; however, it is admitted that any new discoveries or future medical breakthroughs which may occur are difficult to foresee, and consequently they are not taken into account in preparing the mortality projection below.

sex, les facteurs démographiques les plus évidents qui font varier la mortalité sont l'âge et les causes de décès. Parmi les facteurs non démographiques dont l'influence n'est pas facile à évaluer, les plus importants sont les progrès de la médecine, les services hospitaliers et l'assurance-maladie. C'est pourquoi, dans cette étude, nous avons déterminé le rythme de la baisse future de la mortalité au Canada en examinant les tendances passées des trois facteurs démographiques que sont l'âge, le sexe et les causes de décès. Nous espérons que l'analyse par cause de décès traduira dans une large mesure les effets des progrès de la médecine au Canada; toutefois, considérant que les nouvelles découvertes et les progrès futurs dans le domaine médical sont difficiles à prévoir nous ne les avons pas pris en compte dans l'établissement des projections de mortalité ci-dessous.

### Data and Method

In Canada, deaths are classified according to the International Classification of Diseases, Injuries and Causes of Death (ICD). For the purpose of these projections,<sup>2</sup> the various causes of death were divided into the following ten major groups:

1. Infective and parasitic diseases (A1 to A43)
2. Neoplasms (A44 to A60)
3. Allergic disorders and endocrine metabolic and blood diseases (A61 to A66)

### Données et méthode

Au Canada, les décès sont classés suivant la Classification internationale des maladies, traumatismes et cause de décès. Pour les besoins de ces projections<sup>2</sup>, les différentes causes de décès ont été réparties en dix groupes principaux:

1. Maladies infectieuses et parasitaires (A1 à A43)
2. Tumeurs (A44 à A60)
3. Maladies allergiques et endocrinianes, maladies du métabolisme et du sang (A61 à A66)

<sup>2</sup> For more details see a background paper by K.S. Gnanasekaran, *Mortality Projections for Canada and Provinces, 1950-1990*, Statistics Canada (Census), 1973 (Background Paper).

<sup>2</sup> Pour de plus amples détails, consulter l'étude préliminaire de M. K.S. Gnanasekaran *Mortality Projections for Canada and Provinces, 1950-1990*, Statistique Canada (recensement), 1973. (Document non publié.)

4. Diseases of the nervous system and sense organs (A70 to A78)
5. Diseases of the circulatory system (A79 to A86)
6. Diseases of the respiratory system (A87 to A97)
7. Diseases of the digestive system (A98 to A107)
8. Diseases of the genito-urinary system (A108 to A114)
9. Accidents, poisonings and violence (AE138 to AE150)
10. All other causes (A67 to A69, A115 to A137).

In accordance with the conventional period approach adopted here to prepare mortality projections, with the exception of the ninth group regarding accidents (AE138 to AE150), each of the foregoing categories of causes of death was investigated in the same manner and projected on the basis of trends by five-year age groups and sex during 1950-1969.<sup>3</sup> First, the age-sex-disease specific death rates were averaged over the five-year periods 1950-1954, 1955-1959, 1960-1964 and 1965-1969 in order to reduce annual fluctuations in them, and then the percentage increases or decreases in these period rates were calculated over the span of five, ten and fifteen years. Results showed a very consistent pattern in most cases, and therefore it was assumed that the downward or upward trend observed would continue into the future. As to the extent of decline, two assumptions were considered: (a) the same per cent change observed in disease specific rates between 1960-1964 and 1965-1969 would take place in future, and (b) the same per cent change noticed for the longer period from 1955-1959 to 1965-1969 would occur in the coming years. The second assumption was selected here after some evaluation of the projections based on these two hypotheses. The evaluation often took the form of inspecting the pattern and smoothness of the projected mortality curves for each cause according to these two assumptions. Also, the sex differentials by age that emerged under these two hypotheses were examined. In some cases, like cancer mortality, the projected curves were compared with that based on the cohort method.<sup>4</sup> Based on such evaluation for different cause-groups, the second hypothesis involving the trend over a decade 1955-1959 to 1965-1969 was chosen in the present study, and applied to each age-sex specific death rate to yield projections for 1975-1979 and 1985-1989.

<sup>3</sup> Cause of death statistics from 1950 to 1957 were classified according to the Sixteenth Revision (ICD), from 1958 to 1968 according to the Seventeenth Revision, and from 1969 according to the Eighteenth Revision. For this study, data were converted to a standard classification, i.e., the Seventh Revision.

<sup>4</sup> K.S. Gnanasekaran and G. Montigny, "Cancer Mortality in Canada: Trends and Prospects", Paper presented at the Canadian Sociological and Anthropological Association Meetings, Kingston, 1973.

4. Maladies du système nerveux et des organes des sens (A70 à A78)
5. Maladies de l'appareil circulatoire (A79 à A86)
6. Maladies de l'appareil respiratoire (A87 à A97)
7. Maladies de l'appareil digestif (A98 à A107)
8. Maladies des organes génito-urinaires (A108 à A114)
9. Accidents, empoisonnements et violence (AE138 à AE150)
10. Toutes autres causes (A67 à A69, A115 à A137).

Conformément à la méthode transversale conventionnelle adoptée ici pour établir les projections de la mortalité, et à l'exception du neuvième groupe concernant les accidents (AE138 à AE150), tous les groupes de causes de décès ont fait l'objet d'une même analyse puis ont été extrapolés à partir des tendances observées par sexe et par groupe d'âges de cinq ans de 1950 à 1969<sup>3</sup>. On a d'abord calculé la moyenne des taux de mortalité selon l'âge, le sexe et la maladie pour les périodes quinquennales 1950-1954, 1955-1959, 1960-1964 et 1965-1969 dans le but d'en supprimer les variations annuelles. Ensuite on a calculé l'augmentation ou la diminution en pourcentage de ces taux sur une période de cinq, dix et quinze ans. Les résultats ont révélé une tendance très uniforme dans la plupart des cas, ce qui nous amène à présumer que la tendance observée, qu'elle soit à la hausse ou à la baisse, se poursuivra dans l'avenir. Quant à l'ampleur de la baisse, deux hypothèses ont été envisagées: (a) maintien de la variation, en pourcentage, observée de 1960-1964 à 1965-1969, (b) maintien de la variation, en pourcentage, enregistrée sur une plus longue période, soit de 1955-1959 à 1965-1969. Après évaluation des projections, c'est la deuxième hypothèse qui a été choisie. L'évaluation a consisté le plus souvent à examiner l'allure des courbes de mortalité prévues pour chaque cause suivant ces deux hypothèses. On a analysé également les écarts de longévité entre les hommes et les femmes. Dans certains cas, comme les décès dus au cancer, les courbes prévues ont été comparées à celles fondées sur la méthode longitudinale<sup>4</sup>. En fonction de cette évaluation pour différentes catégories de causes, c'est la deuxième hypothèse, basée sur la tendance manifestée au cours de la décennie 1955-1959 à 1965-1969, qui a été choisie dans la présente étude, et appliquée à chaque taux de mortalité selon l'âge et le sexe pour établir les projections de 1975-1979 et de 1985-1989.

<sup>3</sup> Les causes de décès étaient classées suivant la seizième révision (C.I.M.) de 1950 à 1957, suivant la dix-septième révision de 1958 à 1968 et suivant la dix-huitième révision à partir de 1969. Dans cette étude, les données ont été ramenées à une classification uniforme, suivant la septième révision.

<sup>4</sup> K.S. Gnanasekaran et G. Montigny: "Cancer Mortality in Canada: Trends and Prospects", étude présentée au congrès de la Société canadienne de sociologie et d'anthropologie, Kingston, 1973.

For the projection of accident mortality, a linear trend was fitted for each age-sex group by the method of least squares to the time series of specific death rates for 1950-1969. Based on these equations,<sup>5</sup> the mortality levels for Group 9 were projected for the mid-period 1975-1979, and from thereon, the accident mortality was assumed to be constant through 1985-1989.

### Projected Trend and Life Table

The age-sex-cause specific death rates as projected above were added together to arrive at the total mortality of Canada for 1985-1989, shown in Table 3.2 and Chart 3.1. The projections imply an infant mortality rate of 11.5 per 1,000 live births for males and 9.5 for females in 1985-1989. The observed low in 1966 was 10.5 for females in Sweden, and it is possibly lower at present. This rate was 12.5 in the Netherlands for the same period. The assumed level of 9.5 for Canada in 1985-1989 means an arithmetic rate of decrease of 50.2% in twenty years or about 2.5% a year. This tempo of decline in the female infant mortality rate may be regarded as reasonable in the light of the past decline in Canada which amounted to 32.3% in ten years between 1955-1959 and 1965-1969. Moreover, the experiences of lower mortality countries/provinces suggest that the projected rate of decrease in the female infant mortality rate is not something unattainable. For example, Alberta's female infant mortality rate declined by 2.3% (annually) during 1951-1966. Similarly, the Swedish infant mortality rate for females dropped at an average annual rate of 2.5% to the aforementioned level of 10.5 per 1,000 live births between 1948 and 1966, and that of the Netherlands declined at the rate of 2.6% (per year) from 1953-1966.<sup>6</sup>

For males, the projected infant mortality rate is 11.5 in 1985-1989. Sweden recorded the lowest level ever attained thus far, namely, 14.5 in 1966. Nonetheless, the projected level for Canada is viewed as reasonable for the following two reasons. First, judging by historical trends, the male infant mortality rate has always exceeded the female rate by about one-fifth to one-third. On this basis, the assumption made earlier of an infant mortality rate of 9.5 for females in 1985-1989 will suggest a rate somewhere between 11.4 and 12.6 for males. The level of 11.5 implying an excess male mortality of 21% is, therefore, considered reasonable.

Quant aux projections de la mortalité par accident pour chaque groupe d'âges et chaque sexe et suivant la méthode des moindres carrés, on a ajusté une droite aux séries chronologiques des taux de mortalité de 1950 à 1969. À partir de ces équations<sup>5</sup>, les niveaux de mortalité du groupe 9 ont été extrapolés pour la période 1975-1979 puis maintenus constants jusqu'à 1985-1989.

### Projection des taux et tables de mortalité

Les taux de mortalité selon l'âge, le sexe et la cause de décès tels que projetés ci-dessus ont été additionnés pour obtenir les taux de mortalité pour toutes les causes de décès de 1985 à 1989 qui figurent au tableau 3.2 et au graphique 3.1. Ces projections impliquent un taux de mortalité infantile de 11.5 pour 1,000 chez les hommes et de 9.5 chez les femmes en 1985-89. Le taux le plus bas observé en 1966 était de 10.5 chez les femmes en Suède, et il est peut-être encore plus bas à l'heure actuelle. À la même époque, ce taux était de 12.5 aux Pays-Bas. Le niveau présumé de 9.5 au Canada en 1985-89 représente une diminution de 50.2 % en vingt ans ou de 2.5 % par année. Une telle diminution est plausible si on la compare à la diminution de 32.3 % enregistrée au Canada durant la décennie de 1955-59 à 1965-69. En outre, les niveaux observés dans les pays ou provinces à faible mortalité nous laissent croire que le rythme prévu de diminution du taux de mortalité infantile chez les femmes n'est nullement impossible à atteindre. Ainsi, par exemple, le taux de mortalité infantile chez les femmes en Alberta a diminué de 2.3 % par an de 1951 à 1966. De même, le taux de mortalité infantile chez les femmes en Suède a diminué en moyenne de 2.5 % par année et a atteint un niveau de 10.5 pour 1,000 naissances vivantes de 1948 à 1966; et celui des Pays-Bas a diminué de 2.6 % par an entre 1953 et 1966<sup>6</sup>.

Selon nos projections, le taux de mortalité infantile chez les hommes sera de 11.5 en 1985-89. C'est la Suède qui a enregistré le niveau le plus bas jusqu'ici, soit 14.5 en 1966. Néanmoins, il semble raisonnable de penser que le niveau prévu au Canada sera atteint pour les deux raisons suivantes. Premièrement, à en juger par les tendances passées, le taux de mortalité infantile a toujours été d'environ un cinquième à un tiers plus élevé chez les hommes que chez les femmes. Compte tenu de ce rapport, et en se basant sur l'hypothèse émise plus haut d'un taux de mortalité infantile de 9.5 chez les femmes en 1985-89, le taux correspondant sera de 11.4 à 12.6 chez les hommes. Le niveau de 11.5, qui représente une surmortalité masculine de 21 %, est donc considéré comme raisonnable.

<sup>5</sup> The projection equations are given in the background paper by K.S. Gnanasekaran, *op. cit.*, p. 58. Some non-linear trends may be worth investigating for projections of accident as well as of other causes.

<sup>6</sup> United Nations, *Demographic Year Book*, 1951, 1957 and 1967 (Annual) (New York: United Nations).

<sup>5</sup> Les équations de projection sont données dans l'étude préliminaire de K.S. Gnanasekaran, *op. cit.*, page 58. Certaines tendances non linéaires peuvent valoir la peine d'être étudiées pour établir les projections de décès par accident ou autres causes.

<sup>6</sup> Nations Unies: *Annuaire démographique*, 1951, 1957 et 1967 (Annuel) (New York: Nations Unies).

Rate per 100,000 population  
Taux pour 100,000 habitants

Mortality in ages 1 to 19 is projected to decline at a faster rate than in the past due to a more rapid reduction projected in accident mortality. In contrast, the accident mortality is anticipated to rise slightly for ages 20 through 29. With the exception of ages 20-29, 40-44, and 65-69 for men, mortality is expected to decline in all age groups during the projection period. The decline, as seen in Table 3.2, would be greater among females than males. In Chart 3.1 a comparison is made between the projected mortality pattern and that observed for Canada in 1955-1959 and 1965-1969. An examination of this chart suggests that the projections conform with past patterns and differentials by sex noticed in Canada. Further, Table 3.2 shows the lowest mortality rate observed for each age-sex group in the provinces during 1968-1970. Except for the infant and childhood mortality, it is seen that the projected rates for 1985-1989 will fall behind the observed lowest values, implying that the projection results are not unreasonable.

The prerequisite of population projections is a schedule of probabilities of survivorship at different ages which in turn requires life tables. Using the projected death rates by five-year age groups and sex given in Table 3.2, the abridged life tables for Canada by sex are constructed on the basis of the Greville method.<sup>7</sup> In addition, a life table involving the observed minimum values shown in Table 3.2 for ages 5 and over, and the projected values of 0 and 1-4 for 1985-1989, was calculated for each sex and designated as the Maximum Life Expectancy Table (MLET) for Canada.<sup>8</sup> According to these calculations, the expectation of life at birth would increase to 70.2 years for males and 78.6 for females in 1985-1989. The maximum life expectancy values are estimated around 72.8 years for men and 79.1 years for women. The comparison of the projected values for Canada with the life expectancies projected for other low mortality countries suggests that the female life expectancy would be about the same in Canada, Sweden and Switzerland after 1985. However, Canada's projected male life expectancy falls behind the levels anticipated in these two European countries.

The foregoing life tables readily yield the five-year probabilities of survivorship. However, for the purpose of single year population projections that are made by Statistics Canada, a schedule of single year probabilities of survivorship is obtained from the abridged life table population by using the Sprague multipliers.

<sup>7</sup> A.J. Jaffe, *Handbook of Statistical Methods for Demographers* (Washington, D.C., Government Printing Press, 1953), Chapter 2.

<sup>8</sup> K.S. Gnanasekaran, *Mortality Trends and Projections by Causes of Death in Canada, 1950-1990*, Harvard Actuarial Conference, Boston, 1973, p. 32.

On prévoit que la baisse de la mortalité chez les personnes de 1 à 19 ans s'accélérera en raison d'une baisse plus rapide de la mortalité accidentelle. Par contre, cette dernière augmenterait légèrement chez les personnes de 20 à 29 ans. À l'exception des personnes de 20 à 29 ans, de 40 à 44 ans et de 65 à 69 ans, il est prévu que la mortalité diminuera dans tous les groupes d'âges durant la période de projection. Comme on le voit au tableau 3.2, la diminution sera plus marquée chez les femmes que chez les hommes. Dans le graphique 3.1, une comparaison est établie entre la courbe de mortalité prévue et celles observées au Canada en 1955-59 et 1965-69. On se rend compte que les projections correspondent aux tendances passées et aux écarts selon le sexe qui ont été relevés au Canada. En outre, le tableau 3.2 présente le taux de mortalité le plus bas, selon chaque groupe d'âges et sexe, qui a été enregistré de 1968 à 1970 dans chaque province. À l'exception de la mortalité infantile et celle des jeunes enfants, les taux prévus pour 1985-89 sont supérieurs aux taux les plus bas observés. Cela nous permet de croire que les projections ne sont pas déraisonnables et qu'il est possible de les réaliser à l'échelle nationale.

Pour établir des projections démographiques, il faut tout d'abord avoir des probabilités de survie à divers âges qui elles-mêmes nécessitent des tables de mortalité. En utilisant les taux de mortalité prévus par groupe d'âges quinquennal et par sexe, qui sont donnés au tableau 3.2, on peut établir les tables abrégées de mortalité au Canada, selon le sexe, à partir de la méthode de Greville<sup>7</sup>. En outre, une table de mortalité comprenant les valeurs minimales observées au tableau 3.2 pour les personnes de 5 ans et plus, et les valeurs prévues pour celles de 0 et de 1 à 4 ans pour 1985-89 a été établie pour chaque sexe. Elle constitue la table d'espérance de vie maximale au Canada<sup>8</sup>. D'après ces calculs, l'espérance de vie à la naissance serait portée à 70.2 ans chez les hommes et à 78.6 ans chez les femmes en 1985-89. L'espérance de vie maximale est estimée à environ 72.8 ans pour les hommes et à 79.1 ans pour les femmes. La comparaison entre les projections faites pour le Canada et celles faites dans d'autres pays à faible mortalité indique que l'espérance de vie des femmes sera après 1985 à peu près la même au Canada, en Suède et en Suisse. Toutefois, l'espérance de vie des hommes serait plus basse au Canada que dans ces deux pays européens.

Les tables de mortalité précédentes donnent directement les probabilités de survie par groupe d'âges de cinq ans. Cependant, pour les besoins des projections démographiques sur une seule année faites par Statistique Canada, les probabilités de survie par année d'âge ont été obtenues à l'aide des multiplicateurs de Sprague à partir de la table de mortalité abrégée.

## Provincial Differences and Projections

Historically, three provinces, namely, Manitoba, Saskatchewan and Alberta, have had lower mortality or in other words, higher expectation of life at birth than that of Canada. In 1931, the expectation of life at birth in these provinces was 63.5 years for males and 65.5 years for females as compared to 60.0 and 62.1 years respectively for Canada as a whole. It can be seen from Chart 3.2 that although this differential has persisted throughout the subsequent three decades, it has narrowed considerably. Currently, these provinces have an expectation of life at birth which is only slightly higher than the national level. British Columbia also belonged to this group of provinces with a life expectancy above the national average, but this differential has not been as marked as in the Prairie provinces.

In 1951, Ontario's life expectancy was above-average for females and males. In contrast, since 1931 Quebec has had a life expectancy that was lower than the national average for both men and women. However, its mortality situation has been improving faster over the past decades, and consequently the differential has narrowed substantially. Thus, the life expectancy in Quebec was lower than the national level by 3.8 years for males and 5.3 years for females in 1931, whereas this difference was 0.8 and 1.3 years respectively in 1966.

The mortality situation in the Atlantic Provinces was about the same as or slightly different from the national condition in 1966. Life expectancy was lower for males in Prince Edward Island and Nova Scotia and slightly better in Newfoundland and New Brunswick. For females, the level was lower in Newfoundland, Prince Edward Island, and Nova Scotia. The life expectancy in New Brunswick was about equal to the national average of 75.2 years for females in 1966.

No life table is available for the Yukon and Northwest Territories. Estimates indicate that the life expectancy in these areas is far below the national average. These differentials are assumed here to converge gradually in future and the expectation of life at birth by 1986 is projected to be 68.0 years for males and 73.0 for females in the Yukon, and 65.7 and 71.0 years for males and females respectively in the Northwest Territories.<sup>9</sup>

The technique of preparing mortality projections for the provinces involved the ratio method. The ratio of life expectancy in specific province to that of

<sup>9</sup> For method of estimation and life table values, see the background paper by K.S. Gnanasekaran, *op. cit.*, pp. 38-40.

## Projection de la mortalité au niveau provincial

Dans le passé, trois provinces canadiennes, le Manitoba, la Saskatchewan et l'Alberta, ont enregistré un faible niveau de mortalité et une espérance de vie à la naissance beaucoup plus élevée que celle du Canada. En 1931, l'espérance de vie à la naissance dans ces provinces était de 63.5 ans pour les hommes et de 65.5 ans pour les femmes comparativement à 60.0 et 62.1 ans respectivement pour l'ensemble du Canada. On peut voir d'après le graphique 3.2 que même si un écart a continué d'exister pendant les trois décennies suivantes il a quand même été réduit considérablement. Actuellement, l'espérance de vie à la naissance de ces provinces est à peine supérieure à celle de l'ensemble du pays. La Colombie-Britannique faisait également partie de ce groupe de provinces dont l'espérance de vie est supérieure à la moyenne nationale, mais l'écart n'a pas été aussi marqué que dans les provinces des Prairies.

En 1951, l'espérance de vie en Ontario était supérieure à la moyenne chez les femmes et chez les hommes. Au Québec par contre, depuis 1931 l'espérance de vie a toujours été inférieure à la moyenne nationale tant chez les hommes que chez les femmes. Toutefois, la mortalité dans cette province a régressé plus rapidement au cours des dernières décennies, et par suite l'écart observé s'est considérablement amenuisé. Ainsi, l'espérance de vie au Québec était inférieure à la moyenne nationale, de 3.8 ans chez les hommes et de 5.3 ans chez les femmes en 1931, tandis que l'écart n'était plus, respectivement, que de 0.8 et 1.3 an en 1966.

Dans les provinces de l'Atlantique, la mortalité était en 1966 à peu près, sinon la même que dans l'ensemble du pays. Chez les hommes, l'espérance de vie était inférieure dans l'Île-du-Prince-Édouard et en Nouvelle-Écosse, mais légèrement supérieure à Terre-Neuve et au Nouveau-Brunswick. Chez les femmes, elle était inférieure à Terre-Neuve, dans l'Île-du-Prince-Édouard et en Nouvelle-Écosse. Au Nouveau-Brunswick, l'espérance de vie des femmes était en 1966 à peu près équivalente à celle du Canada, soit 75.2 ans.

Il n'existe aucune table de mortalité pour le Yukon et les Territoires du Nord-Ouest. Nos estimations révèlent que l'espérance de vie dans ces régions est bien en dessous de la moyenne nationale. On prévoit que l'écart se rétrécira progressivement dans l'avenir et que d'ici 1986 l'espérance de vie sera de 68 ans pour les hommes et de 73.0 ans pour les femmes au Yukon, et de 65.7 et 71.0 ans pour les hommes et les femmes respectivement dans les Territoires du Nord-Ouest<sup>9</sup>.

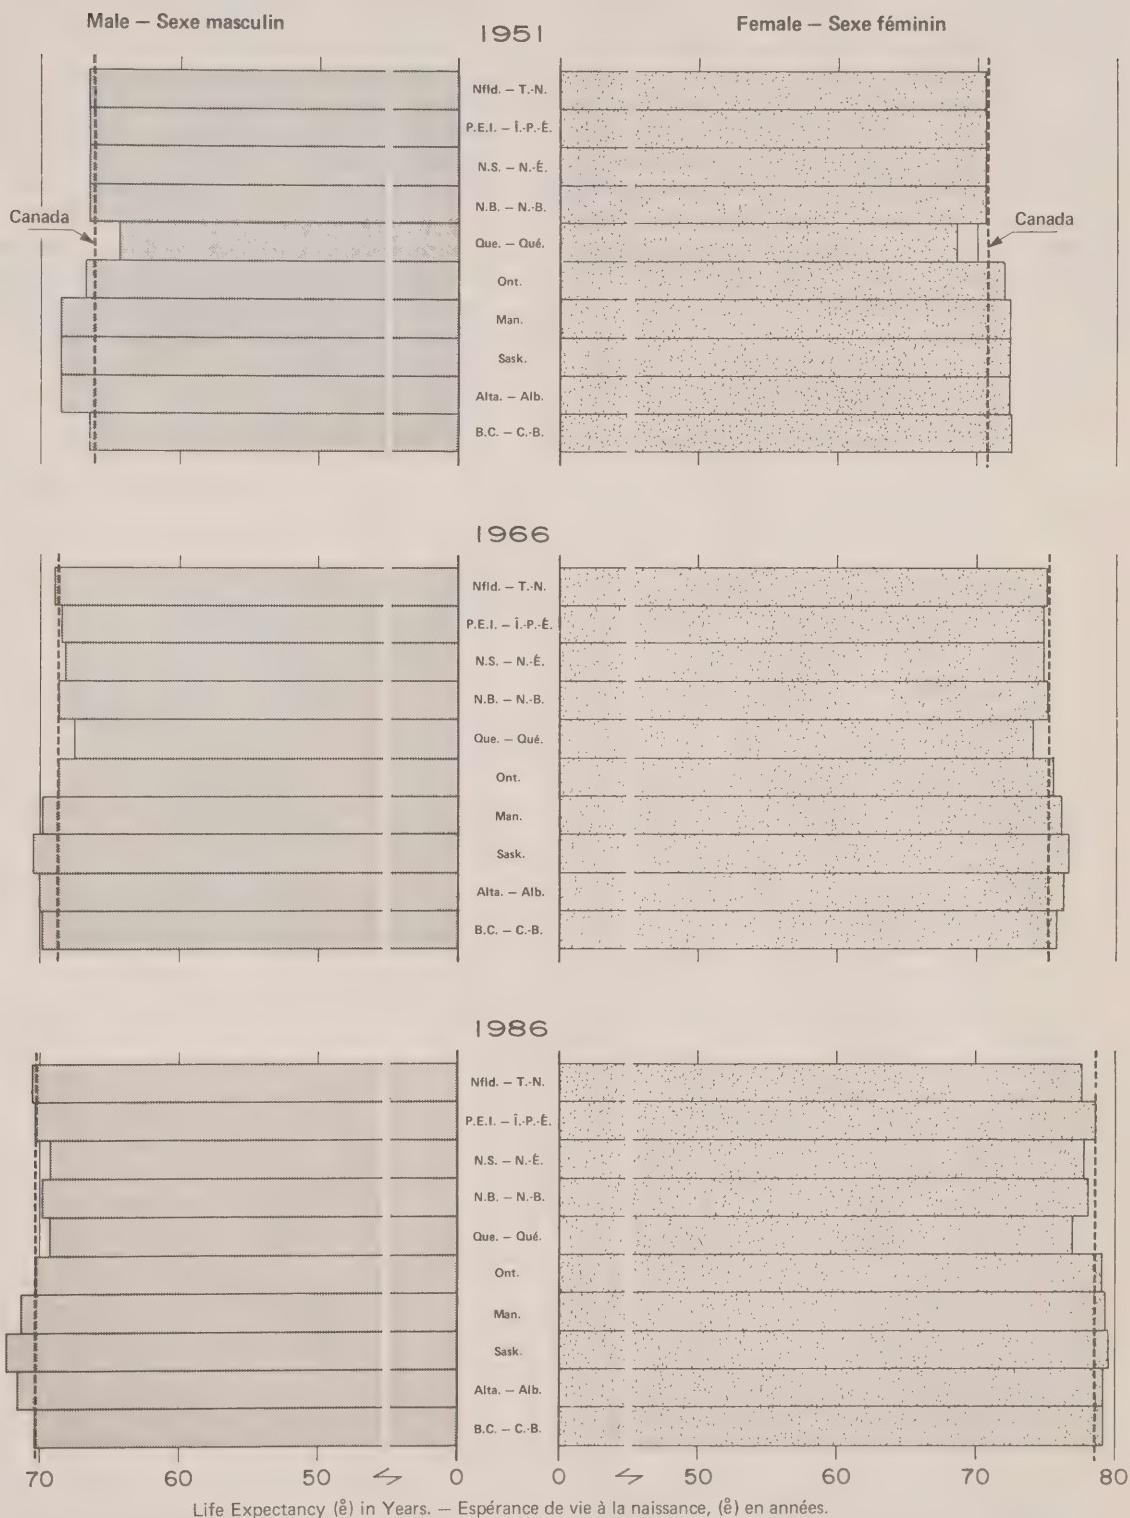

Pour établir les projections de la mortalité dans les provinces, on a eu recours à la méthode des rapports. Le rapport de l'espérance de vie dans chaque province à celle

<sup>9</sup> L'étude préliminaire de M. K.S. Gnanasekaran, *op. cit.* (pages 38 à 40) donne la méthode d'estimation ainsi que les tables de mortalité.

**Chart 3.2**

## Mortality Trends and Differentials by Provinces, 1951, 1966 and 1986 Évolution de la mortalité différentielle, Canada et provinces, 1951, 1966 et 1986

### Graphique 3.2

Life Expectancy ( $\hat{e}$ ) in Years. — Espérance de vie à la naissance, ( $\hat{e}$ ) en années.

Canada in the recent period 1968-1970 was consistent with the pattern observed in the preceding periods. It is therefore assumed that this relative mortality situation would continue in the future, and for purpose of projections, the ratios for the period 1968-1970 were applied to the projected expectation of life at birth for Canada. This procedure yielded the mortality projections for each province in terms of expectation of life at birth, as shown in Table 3.3. The survival probabilities that correspond to these life expectancy values were obtained by reference to the projected national life table for 1975-1979, 1985-1989 and also the Maximum Life Expectancy Table. Using the official life table for 1965-1967 as the base and the foregoing tables, the survival ratios (i.e.  $S_x$  values) were calculated by linear interpolation for 1971, 1976, 1981 and 1986.

dans l'ensemble du Canada, au cours de la période 1968-1970, était comparable à ceux observés au cours des périodes antérieures. On a donc supposé que ces rapports de mortalité se maintiendraient dans le futur et, pour les besoins de ces projections, les rapports observés pour la période 1968-1970 ont été appliqués à l'espérance de vie à la naissance prévue pour le Canada. On a ainsi obtenu les projections de la mortalité pour chaque province, exprimées en fonction de l'espérance de vie à la naissance (voir tableau 3.3). Les probabilités de survie qui correspondent aux niveaux prévus de l'espérance de vie ont été calculées à partir de la table de mortalité nationale pour 1975-1978 et 1985-1989, ainsi qu'à l'aide de la table d'espérance de vie maximale. À partir de la table de mortalité officielle pour 1965-1967 ainsi que des tables mentionnées précédemment, on a calculé les probabilités de survie (c.-à-d. les valeurs de  $S_x$ ), par interpolation linéaire, pour 1971, 1976, 1981 et 1986.

## CHAPTER 4

### Fertility Projections

#### Methodology

The conventional approach to birth projection is to project age-specific fertility rates by calendar years. These rates can be projected either directly or derived indirectly by first projecting cohort fertility rates. The first is known as the "period fertility method", and the second as the "cohort fertility method". Both these methods have been used in the past to produce population projections by Statistics Canada.

The approach underlying the present projections departs considerably from the conventional methods mentioned above. Instead of projecting calendar year age-specific fertility rates, these are derived, through a specially devised model<sup>1</sup> from only three simple period fertility measures, namely (1) total fertility rate, (2) mean age, and (3) mode age of fertility. In this model, the total fertility rate is a parameter of the over-all level of fertility, while the mean and mode ages are parameters of its age distribution. The reduction in the number of fertility parameters offers appreciable operational and analytical advantages. One significant advantage is that statistical operation is confined to only three fertility measures which are most appropriate for an indepth analysis required to provide rationales for assumptions of future fertility.

The formulation of assumptions regarding the future trends of these three parameters involved a detailed examination of a wide range of longitudinal data on fertility. Thus, to project the future total fertility rate, assumptions concerning the timing of childbearing and the family size of cohorts of mothers are to be made which, in turn, raises questions such as whether the current fertility decline is due to a postponement of births which is an aspect of timing of fertility, or to the fact that couples, currently of the reproductive ages, intend to have fewer children than their predecessors, thereby curtailing their family size. No definite answers to these questions can be offered until these couples have completed their childbearing cycle. However, certain reasonable inferences that are instrumental in the formulation of assumptions regarding the total fertility over the next few years can be made from observed tendencies. If indeed there are valid reasons to believe that postponement of births is at least partly responsible for the current fertility decline, then making up for the postponement at a later date will result in an increase in the period total

## CHAPITRE 4

### Projection de la fécondité

#### Méthodologie

La méthode classique pour établir les projections de naissances consiste à projeter les taux de fécondité selon l'âge par année. Ces taux peuvent être projetés directement ou indirectement en projetant d'abord les taux de fécondité des générations. La première façon est connue sous le nom de "méthode transversale", et la deuxième est appelée "méthode longitudinale". Ces deux méthodes ont déjà été utilisées par Statistique Canada pour établir des projections démographiques.

La méthode qui a servi à établir les présentes projections s'écarte considérablement des méthodes classiques mentionnées ci-dessus. Au lieu de projeter les taux de fécondité du moment, on les obtient à l'aide d'un modèle original<sup>1</sup>, à partir de seulement trois mesures simples de la fécondité, soit (1) l'indice synthétique de fécondité, (2) l'âge moyen et (3) l'âge modal à l'accouchement. Dans ce modèle, l'indice synthétique de fécondité est une mesure du niveau de la fécondité, tandis que les âges moyen et modal sont des mesures de son calendrier. La réduction du nombre des paramètres de la fécondité offre des avantages considérables du point de vue opérationnel et analytique. Un avantage important réside dans le fait que le traitement statistique se limite à trois mesures de fécondité seulement, dont toutes conviennent particulièrement bien pour l'analyse approfondie nécessaire afin d'étayer les hypothèses de fécondité future.

La formulation des hypothèses concernant ces trois paramètres a nécessité l'examen approfondi d'un vaste éventail de données longitudinales sur la fécondité. Ainsi, pour établir une projection de l'indice synthétique de fécondité, il a fallu faire des hypothèses sur le calendrier des naissances et la descendance finale des générations. Sous ce rapport, nous nous sommes demandés si la diminution actuelle de la fécondité est attribuable à un allongement du calendrier, c'est-à-dire à un ajournement des naissances, ou au fait que les couples, actuellement en âge de procréer, désirent avoir moins d'enfants que leurs prédecesseurs, réduisant par le fait même la dimension de leur famille. Aucune réponse définitive ne peut être donnée à ces questions tant que ces couples ne sont pas arrivés à la fin de leur période de procréation. Cependant, de l'observation des tendances passées il est possible de tirer certaines indications quant à l'évolution de la fécondité des prochaines années. En effet, s'il y a de bonnes raisons de croire que l'ajournement des naissances est, au moins en partie, responsable de la diminution récente de la fécondité, alors la récupération des naissances ainsi ajournées doit entraîner une augmentation de

<sup>1</sup> For a complete description of the model, see A. Romaniuk, "A Three Parameter Model for Birth Projections", *Population Studies*, Vol. XXVII, No. 3, November 1973, pp. 467-478.

<sup>1</sup> Voir la description complète du modèle dans l'article de A. Romaniuk "A Three Parameter Model for Birth Projections", *Population Studies*, Vol. XXVII, no 3, novembre 1973, pages 467-478.

fertility rate. In brief, assumptions on the level (family size) and timing or age pattern of fertility, by generations (cohorts) of mothers as opposed to a cross-sectional analysis of period rates.

Furthermore, to provide more depth to the analysis of cohort fertility, considerable reliance was placed on data on fertility by birth order (i.e. parity distribution). Indeed, to make assumptions about cohort fertility levels, it is important to make assumptions about the proportions of women who upon completion of their childbearing, would have at least one, two, three and four or more children. By definition the sum of these proportion is the average number of children per woman having completed her fertility. Data on parity distribution in turn provide a suitable springboard for analysis in terms of the various social, economic and medical factors affecting procreation. For example, the proportion of women who will have at least one child depends on factors such as the proportion of women who marry before reaching menopause, their age at marriage, and the incidence of sterility which in turn partially depends on the state of medical technology. The formulation of assumptions regarding the timing and age pattern of cohort fertility, was based on the analysis of age patterns of fertility by birth order, child spacing (intervals between successive births) and age patterns of nuptiality rates.

In short, from the analysis of cohort fertility by birth orders it was possible to derive assumptions about the timing or age pattern and the level of fertility for successive cohorts. The mean age of fertility was used as a measure of timing and the completed fertility rate as a measure of cohort fertility level (family size). A model, which is essentially an adaptation by D. Vanasse-Duhamel of Ryder's translation model<sup>2</sup> was applied to translate the cohort measure just mentioned into period total fertility rate.<sup>3</sup>

l'indice synthétique de fécondité. En résumé, l'établissement d'hypothèses sur l'intensité (dimension de la famille) et le calendrier de la fécondité selon l'âge, exige une analyse longitudinale (données de générations) par opposition à l'analyse transversale (données du moment).

Pour analyser plus à fond la fécondité des générations, on a accordé une importance considérable à la fécondité suivant le rang de naissance. Il est important d'établir des hypothèses sur les proportions de femmes qui, au terme de leur période de procréation, auront eu au moins un, deux, trois et quatre enfants ou plus. La somme de ces proportions représente, par définition, la descendance finale d'une génération. Les données sur la fécondité selon le rang de naissance constituent un point de départ approprié pour l'analyse des divers facteurs (sociaux, économiques et médicaux) qui influent sur la procréation. Par exemple, la proportion des femmes qui auront au moins un enfant dépend de facteurs tels que la proportion de femmes qui se marieront avant d'avoir atteint la ménopause, leur âge au mariage, et la fréquence de la stérilité, qui, pour sa part, dépend en partie des progrès médicaux. En ce qui a trait à l'élaboration des hypothèses relatives au calendrier de la fécondité des générations, on a eu recours à l'analyse de la fécondité par âge selon le rang de naissance, de l'espacement des naissances (intervalles entre deux naissances successives) et de la structure des taux de nuptialité.

En bref, à partir de l'analyse longitudinale de la fécondité selon le rang de naissance, nous avons pu faire des hypothèses concernant le calendrier des naissances et l'intensité de la fécondité des générations successives. Nous avons pris l'âge moyen à l'accouchement comme mesure de calendrier et la descendance finale comme mesure de l'intensité de la fécondité (dimension de la famille). Un modèle, qui consiste essentiellement en une adaptation par D. Vanasse-Duhamel du modèle de translation de Ryder<sup>2</sup>, nous a permis de transposer les données par génération mentionnées précédemment en indice synthétique de fécondité<sup>3</sup>.

## National Fertility Assumptions

In the model used here to derive future annual births, the most important parameter is the period total fertility rate. Fertility trends in this country, over the last few decades, are characterized by wide fluctuations. From a low of 2.64 births per woman in the depression years of the thirties, the period total fertility rate rose gradually through the baby-boom of

## Hypothèses de fécondité au niveau du Canada

Dans le modèle utilisé pour déterminer le nombre futur de naissances, c'est l'indice synthétique de fécondité qui est le paramètre le plus important. Au cours des dernières décennies, l'évolution de la fécondité au Canada a été caractérisée par d'importantes variations. L'indice synthétique de fécondité, qui était descendu à 2.64 naissances par femme pendant la crise économique des

<sup>3</sup> D. Vanasse-Duhamel, "Le processus de translation comme méthode d'analyse et de projection de la fécondité au Canada", *Bulletin de l'Association des démographes du Québec*, vol. 2, n° 1, pages 82 à 98.

the post-war years to a maximum of 3.95 births per woman in 1959. The total fertility rate since then has fallen to a new low level of only 2.14 births per woman in 1972.

What is likely to be the course of fertility in the years to come? Will fertility continue to decline, stabilize at the current rate, say in the vicinity of replacement level (2.1 births per woman), or will it rise again, and, if so, to what level? Needless to say, in attempting to project future trends with any degree of certainty, the analyst is faced with a difficult if not an impossible dilemma. A simple extrapolation of current trends, often adopted in projections, is not warranted if a lesson has to be learned from past experiences.

Certain assumptions may, however, appear to be more plausible than others when based on a careful scrutiny of relevant facts and indications. A new baby-boom of the magnitude that occurred in the fifties, seems highly improbable in the foreseeable future for reasons given later in this chapter. On the other hand, in a society that remains basically a familistic one few would venture in anticipating an extremely low fertility. There seems to be a tendency toward more homogeneous procreative behaviours in terms of the number of children per couple, and a shift toward a family composition centered on two rather than on three children. As an authority in the field puts it, the trends denote "the extraordinary extent to which the population is becoming more homogeneous in the number of births per marriage".<sup>4</sup> The implication may be that while fertility is bound to fluctuate, it may do so within a narrower range than in recent decades. For reasons that will become more apparent as this analysis progresses, it is assumed for the present projections that a range of fertility from 1.80 to 2.60 births per woman will be reached in the late seventies or the early eighties.

Table 4.1 reveals the kind of parity structure consistent with the assumed relatively high (2.60) and relatively low (1.80) total fertility rate. Of course, the actual values may depart more or less from the ones projected here. The purpose of this table is to demonstrate the kind of shifts in the parity distribution that are required if a certain family size is to be achieved. For example, in view of what seems to be a strong downward trend of fertility at higher birth orders (4 and over) it appears that in order to achieve a family size of 2.60 children the proportion of women

années 30, a progressivement augmenté et, avec l'explosion démographique de l'après-guerre, a atteint le niveau record de 3.95 naissances par femme en 1959. Depuis lors on a assisté à une baisse du niveau de fécondité et en 1972, l'indice synthétique de fécondité au Canada était descendu à un nouveau minimum de 2.14 naissances par femme.

Quel sera le niveau de fécondité dans les années à venir? Le taux de fécondité continuera-t-il à diminuer, se maintiendra-t-il au niveau actuel, disons aux environs du niveau de remplacement (2.1 naissances par femme), ou augmentera-t-il à nouveau et, dans ce cas, quel niveau atteindra-t-il? Il va sans dire que dans toute tentative de prévoir avec une certaine précision l'évolution future, l'analyste se trouve placé devant un choix difficile sinon impossible à faire. Si l'on se fie à l'expérience, la simple extrapolation des tendances passées, méthode souvent utilisée dans les prévisions, n'est pas une solution.

Certaines hypothèses peuvent toutefois sembler plus plausibles que d'autres lorsqu'elles sont fondées sur un examen minutieux des faits pertinents. Un nouveau "baby boom" comparable à celui des années 50 semble fort peu probable dans un avenir prévisible, pour des raisons qui seront exposées plus loin. D'autre part, dans une société dans laquelle la famille joue toujours un rôle important, on se garderait de prévoir un niveau de fécondité extrêmement bas. On observe une tendance à l'uniformisation des comportements procréateurs en ce qui concerne le nombre d'enfants par famille et une réduction de la dimension de la famille de trois à deux enfants. Comme le dit un spécialiste de la fécondité: "la population se dirige vers une uniformité remarquable quant au nombre d'enfants par couple"<sup>4</sup>. Bien que le niveau de fécondité soit appelé à fluctuer, les variations en seront probablement moins marquées que par le passé. Pour les besoins des présentes projections et pour des raisons qui deviendront plus évidentes au fur et à mesure du développement de cette analyse, on prévoit que l'indice synthétique de fécondité se situera entre 1.80 et 2.60 naissances par femme d'ici la fin des années 70 ou le début des années 80.

Le tableau 4.1 montre le genre de structure selon le rang de naissance compatible avec les niveaux de fécondité prévus: relativement élevé (2.60) et relativement bas (1.80). Naturellement, la réalité pourra s'écarte plus ou moins de ces projections. Ce tableau vise à démontrer quel genre de changement doit être apporté dans la répartition selon le rang pour obtenir une certaine dimension de famille. Par exemple, du fait de la tendance apparemment irrésistible vers une baisse de la fécondité dans les rangs de naissance les plus élevés (4 enfants et plus) la proportion des femmes ayant au moins un ou deux enfants doit être

having at least one and two children must be as high as that prevalent among the cohorts born around 1930. By contrast, if family size is to settle down at a level as low as 1.80, the proportion of women having at least one child would probably drop to something like 75%.

aussi élevée que celle des générations nées aux environs de 1930 pour obtenir une famille de 2.60 enfants. Par contre, si la dimension de la famille doit se maintenir à un niveau aussi bas que 1.80, la proportion des femmes ayant au moins un enfant diminuerait probablement à environ 75 %.

The first two birth orders are the most critical variables in projecting future family size. Expectations of high or low future trends in the initial two fertility orders may find some valid justification in the analysis of parity data. Indeed, there are good reasons to assume a continuation of a high fertility level for the first two birth orders. Marriage continues to take place at fairly young ages in Canada, females remaining single are few, and there is no indication of any reversal in this respect. Medical progress to cure physiological sterility along with the important advances made in artificial insemination, can result in further reduction of involuntary childlessness. Psychological propensity for motherhood remains strong among North American women,<sup>5</sup> although the desired or intended family size may have diminished among the younger as compared to the older generations. All surveys on prospective fertility carried out in the United States and Canada in recent years reveal that women, including the youngest, generally express their intentions to have at least two children. On the average, total births expected by wives aged 18 to 24 in a survey by the U.S.

Les deux premiers rangs de naissance constituent les facteurs les plus importants dans la prévision de la dimension future de la famille. Les perspectives tant fortes que faibles de ce qu'en sera l'évolution future peuvent toutes deux se justifier à la lumière des données de base. En effet, il y a de bonnes raisons de croire que la fécondité se maintiendra à un niveau élevé pour les deux premiers enfants. L'âge au mariage demeure à un niveau assez bas au Canada, les femmes qui restent célibataires sont peu nombreuses, et rien n'indique un renversement de la situation. Les progrès de la médecine pour remédier à la stérilité physique ainsi que les découvertes importantes dans le domaine de l'insémination artificielle feront que l'infécondité volontaire diminuera encore davantage. La propension psychologique à la maternité est encore forte chez les femmes de l'Amérique du Nord<sup>5</sup>, même si la dimension souhaitée ou prévue de la famille a diminué chez les jeunes générations par rapport aux anciennes. Toutes les enquêtes sur les perspectives d'avenir de la fécondité effectuées ces dernières années aux États-Unis et au Canada révèlent que les femmes, même les plus jeunes, ont en général l'intention d'avoir au moins

Bureau of the Census in 1972<sup>6</sup> were 2.3, a drop from 2.9 reported by a similar survey in 1967.

Although there are substantial reasons for assuming a continuation of high fertility levels for the first two birth orders, there are other factors prevalent in Canadian society which may promote more widespread childlessness and serve to further reduce family size. Some of these factors are greater access to more efficient contraceptive techniques, the promotion of family planning, and greater public awareness of problems associated with population growth.

An additional factor which deserves special consideration in this regard is the increasing participation of females in the labour force.<sup>7</sup> The participation rate of married women increased from 11.2% in 1951 to 22.0% and 37.0% in 1961 and 1971 respectively. In 1971, 62% of all women aged 20-24 were in the labour force, compared to 50% in 1961 and 49% in 1951.<sup>8</sup> In spite of the abundant literature on the subject,<sup>9</sup> the exact relationship between female labour force participation and fertility still remains unclear, though one is inclined to view the former as having a depressing effect on the latter. Perhaps more important than the sheer increase in the number of working women is the apparent expansion of "professionalism" among women.

One should not view the range of 1.80 to 2.60 births per woman implied in these projections as the "minimum" or "maximum" expected fertility levels in an absolute sense, but merely as the range which is most likely to encompass the actual fertility in Canada over the next decade. In fact, as a result of the combined effect of recuperation and acceleration of

deux enfants. En moyenne, le nombre total de naissances prévu par les épouses âgées de 18 à 24 ans interrogées lors d'une enquête menée par le U.S. Bureau of the Census en 1972<sup>6</sup> était de 2.3, comparativement à la moyenne de 2.9 obtenue lors d'une enquête analogue menée en 1967.

Bien qu'il y ait des raisons importantes de supposer que les niveaux de fécondité continueront à être élevés pour les deux premiers rangs de naissances, il existe au Canada d'autres facteurs qui pourraient favoriser une infécondité plus grande et contribuer à réduire davantage la dimension de la famille. Certains de ces facteurs comme une plus grande accessibilité à des méthodes contraceptives efficaces, l'encouragement à la planification familiale ainsi qu'une meilleure sensibilisation du public à l'égard des problèmes liés à la croissance démographique, prendront probablement plus d'importance dans l'avenir.

Un autre facteur auquel on doit accorder une attention spéciale à ce point de vue, est l'augmentation constante des taux d'activité chez les femmes<sup>7</sup>. Le taux d'activité des femmes mariées est passé de 11.2 % en 1951 à 22.0 % en 1961 et à 37.0 % en 1971. En 1971, 62 % de l'ensemble des femmes âgées de 20 à 24 ans faisaient partie de la population active comparativement à 50 % en 1961 et à 49 % en 1951<sup>8</sup>. Malgré tout ce qui a été écrit sur ce sujet<sup>9</sup>, il est encore impossible de déterminer avec exactitude le sens de la relation entre les taux d'activité féminins et la fécondité, bien qu'on soit porté à penser que le premier facteur n'est pas de nature à favoriser le second. En fait, l'apparition d'un véritable "professionnalisme" chez les femmes de notre société est peut-être un facteur plus important que la simple augmentation du nombre des femmes actives.

Il ne faut pas considérer les niveaux de 1.80 à 2.60 naissances par femme avancés dans ces projections comme des niveaux absous, mais simplement comme l'éventail probable des taux de fécondité au Canada au cours de la prochaine décennie. En fait, sous l'effet combiné de la récupération et du rajeunissement de la fécondité des générations, l'indice synthétique de fécondité pourrait

fertility, the total fertility rate may temporarily exceed the 2.60 births. This proposition requires further elaboration.

Some demographers<sup>10</sup> argue, on the basis of indirect evidence from data on timing and childbearing age patterns among younger generations, that the current fertility decline to some extent may be due to birth postponements. Indeed, there seems to be a tendency among younger Canadian generations to have children at somewhat older ages and at somewhat longer intervals.<sup>11</sup> If this thesis of postponement is proved to be correct, then other things being equal, the recuperation of the postponed births should produce a corresponding rise in the total fertility rate.

Furthermore, if the upward shift in childbearing ages is a temporary phenomenon, and should youthful generations revert to earlier habits of having children at younger ages, then this so-called fertility acceleration process should also give rise to an increase in the total fertility rate. The combination of these two factors – making up for the postponed births among the older and the earlier motherhood among the younger generations – could result in a phenomenon of piling up of births similar to, but on a much smaller scale than, that which occurred in the post-war years. It is estimated that as a result of this combined process, the total fertility rate could rise to about 2.9 births. However, should this **mini-baby-boom** occur, it is unlikely to extend beyond the period required for the recuperation process to be completed.

At any rate, in order for the family size to settle at well above the assumed 2.6 births per woman, the fertility of the first two birth orders would not only have to remain at its highest plateau (see Table 4.1), but fertility of the upper orders (from 4th on) would also have to increase substantially from its current level. For many generations now there has been a clear-cut tendency toward reduction in the proportion of women with 4 and more births. Consequently, in light of past and recent trends, it is unlikely that there would be a substantial increase in fertility levels of the upper orders.

The lower level of fertility assumptions implied in these projections is subject to even greater uncertainties than the upper one. This is because the current fertility decline is too novel a phenomenon,

dépasser temporairement les 2.60 naissances. Cette supposition demande un peu plus d'explication.

Se fondant sur la répartition des naissances selon l'âge chez les jeunes générations certains démographes<sup>10</sup> attribuent dans une certaine mesure la diminution actuelle de la fécondité à un ajournement des naissances. En effet, il semble y avoir chez les jeunes générations canadiennes une tendance à avoir des enfants à un âge plus avancé et à des intervalles plus longs<sup>11</sup>. Si cette thèse du report des naissances est fondée, alors, si les autres facteurs sont inchangés, la récupération des naissances qui ont été retardées devrait se traduire par une augmentation correspondante de l'indice synthétique de la fécondité.

De plus, si l'augmentation de l'âge à l'accouchement est un phénomène passager, et que les jeunes générations reviennent à l'habitude d'avoir leurs enfants à un âge plus précoce, nous assisterions également à un accroissement de l'indice synthétique de fécondité. L'action conjuguée de ces deux facteurs, soit la récupération des naissances retardées chez les couples plus âgés et un âge moyen à l'accouchement plus précoce chez les jeunes générations, aboutira peut-être à une concentration de naissances analogue, mais à une échelle beaucoup plus réduite, au phénomène qui s'est produit durant les années d'après-guerre. On pense qu'avec la combinaison de ces deux facteurs, l'indice synthétique de fécondité pourrait atteindre environ 2.9 naissances. Cependant, si cette **mini-explosion démographique** se produisait, il est peu probable qu'elle s'étende au-delà de la période de récupération.

De toute façon, pour que la dimension de la famille se maintienne bien au-dessus du niveau de 2.6 naissances par femme, la fécondité des deux premiers rangs de naissances devrait non seulement se maintenir à son plus haut niveau (voir tableau 4.1), mais encore la fécondité des derniers rangs (à partir du 4e enfant) devrait également augmenter considérablement par rapport à son niveau actuel. Depuis de nombreuses générations, la proportion des femmes donnant naissance à 4 enfants et plus est en nette régression. Une augmentation importante de la fécondité des rangs élevés est, par conséquent, peu probable.

Dans ces projections de fécondité l'hypothèse faible risque beaucoup plus d'être erronée que l'hypothèse forte. La raison en est que la baisse actuelle de la fécondité est un phénomène trop nouveau et que nous ne disposons pas

<sup>11</sup> See discussion of age pattern of fertility later in this chapter.

and because one lacks the proper time perspective to comprehend the extent and nature of changes in the procreative behaviours that are taking place in the society. Temporarily, the total fertility rate can drop to 1.8 and even to a lower level, as in Quebec where it has already fallen to 1.7. One should however, not confuse the total fertility rate in a given period of time with the level of fertility, i.e., the family size that the real cohorts of women may achieve upon completion of their childbearing cycle.<sup>12</sup> Quite a substantial reduction in the period total fertility may occur as a result of upward shifts in the timing of childbearing and of birth postponements, but in the long run a low total fertility rate cannot be achieved without a corresponding reduction in the family size of the relevant cohorts.

In Table 4.1 it was seen that a family size of only 1.8 children implies that about 25% of women remain childless. Such a level of childlessness is rather high, at least when gauged against the background of historical precedence.<sup>13</sup> Widespread childlessness would not become a lasting feature of Canadian society without a large scale re-evaluation of the generally accepted fertility norms. Nothing now permits one to conclude that such a re-evaluation is in the process of becoming a reality. On the contrary, all fertility surveys undertaken in recent years reveal that there is still a strong aversion to childlessness and to one-child families among North American women. In a recent article, Judith Blake notes that

"A willingness to regard childlessness and the only child as desirable or even acceptable is still rare . . . Regardless of the nature of white Americans' motives for preferring smaller families in recent years, people do not feel impelled to redefine their views on childlessness and the one-child family. This conclusion emerges from a number of different types of survey data."<sup>14</sup>

Even in such an atypical population as college students, only about 10% of the students interviewed favoured childlessness and an only child. No one can say to what extent the expressed preferences or aversions for particular family sizes are normative of actual procreative behaviours.

<sup>12</sup> It is quite possible that when the generations in Quebec currently involved in childbearing reach the end of their childbearing, they will have more than 1.7 children on the average.

<sup>13</sup> In the thirties, childlessness was estimated at about 20%. About half of this proportion was due to the high proportion of single women. It may be assumed that quite an important component of childlessness was physiological sterility.

<sup>14</sup> Judith Blake, *op. cit.*, p. 33.

d'un recul suffisant pour déterminer la signification des changements du comportement procréateur qui se produisent dans notre société. À court terme, l'indice synthétique de fécondité peut descendre à 1.8 et même plus bas, comme cela s'est produit au Québec où le taux est déjà tombé à 1.7. Il ne faut pas confondre l'indice synthétique de fécondité (une mesure du moment) avec le niveau de la fécondité, c'est-à-dire la dimension de la famille que les générations atteindront une fois leur période de procréation terminée<sup>12</sup>. Une réduction considérable de l'indice synthétique de fécondité peut se produire si l'on tarde les naissances ou si on les espaces davantage, mais, en fin de compte, l'indice synthétique de fécondité ne restera faible que s'il y a réduction correspondante de la dimension finale de la famille des générations en cause.

Dans le tableau 4.1, on a vu que pour arriver à une moyenne de 1.8 enfant seulement par famille, il faut qu'environ 25 % des femmes n'aient pas d'enfant. Un tel niveau d'infécondité est relativement élevé, surtout si on le compare à ce qu'il était dans le passé<sup>13</sup>. Il est peu probable que l'infécondité se généralise dans notre société sans que n'ait lieu une réévaluation profonde des normes de fécondité généralement admises. Rien n'indique pour l'instant qu'une telle réévaluation soit en cours. Au contraire, toutes les enquêtes sur la fécondité effectuées ces dernières années révèlent que les femmes en Amérique du Nord sont encore fortement opposées à l'idée d'infécondité et au concept de familles sans enfant ou à un seul enfant. Dans un article récent, Judith Blake fait remarquer ce qui suit:

"La volonté de n'avoir qu'un seul enfant ou de n'en pas avoir ou même simplement l'idée d'envisager une telle situation, est encore très peu répandue . . . Quelle que soit la nature des motifs qui ont incité la population américaine de race blanche à préférer des familles peu nombreuses ces dernières années, les gens ne se sentent pas pour autant amenés à redéfinir leur position quant à la famille sans enfant ou à enfant unique. Telle est la conclusion qui ressort de différentes enquêtes<sup>14</sup>".

Même au sein d'une population aussi peu représentative que des étudiants de niveau collégial, seulement 10 % environ des étudiants interviewés étaient en faveur de la famille sans enfant ou à enfant unique. Personne ne peut dire dans quelle mesure les comportements procréateurs rendront compte des préférences exprimées pour telle ou telle dimension de famille.

<sup>12</sup> Il est fort possible que lorsque les générations du Québec actuellement en âge de procréer seront arrivées au terme de leur période de procréation elles aient en moyenne plus de 1.7 enfant.

<sup>13</sup> Dans les années 30, environ 20 % des femmes n'avaient pas d'enfant. La moitié environ de cette infécondité s'explique par la forte proportion de femmes célibataires. On peut présumer qu'un bon pourcentage des autres femmes sans enfant ont été infécondes pour cause de stérilité physiologique.

<sup>14</sup> Judith Blake, *op. cit.*, page 33.

The remainder of this section is devoted to two parameters of the age pattern of fertility, namely, the mean and mode ages. As determinants of the total number of births, these parameters play in the present projection model, a secondary role in comparison with the total fertility rate, and therefore will be dealt with only briefly.

Analysis of both cross-sectional and cohort data reveals a downward tendency in the age of marriage and childbearing. As shown in Table 4.2, the period mean age of fertility gradually went down from 30 years in the 1930's to 27.0 in 1971, and the period mode age decreased from nearly 28 to 23.3 years. This downward shift in the age pattern of family building was an important factor in the post-war baby-boom which lasted until 1960. Not only did people marry at an earlier age but they had children at increasingly shorter intervals.

The picture regarding the timing and age pattern of childbearing in more recent years is somewhat confusing. On the one hand, the 1960's cross-sectional data suggest a slowdown in the downward shift in the age pattern of childbearing, which is especially apparent in the time trends exhibited by the mode age. On the other hand, longitudinal (cohort) data, unfortunately still incomplete, point not only to a slowdown but also to a reversal in this movement. The mean age of the first and second birth orders has slightly increased among cohorts of women born in the first half of the forties (who entered childbearing ages in the sixties), and the mean intervals between marriage and the first birth and between the first and second birth also seem to have increased.<sup>15</sup> Similar changes in the timing and age structure of family formation seem to have occurred in the U.S. as well.

Different explanation for this upward shift (real or apparent) in the age pattern of family formation can be offered. Access to more efficient contraceptives is said to have had a delaying effect on marriage and births, due to the avoidance of some "unwanted" pregnancies which otherwise would have occurred. The phenomenon of the so-called "marriage squeeze", i.e., the disproportion between female and male cohorts in prime marriage ages, has contributed to the slacking of the nuptiality rate observed among young cohorts.<sup>16</sup> It has been argued that additional causes of retardation in family formation may have been economic, such as

Le reste de cette section est consacré à deux paramètres du calendrier de la fécondité, soit l'âge moyen et l'âge modal. En tant que facteurs déterminants du nombre total de naissances, ces paramètres jouent dans le présent modèle de projection, un rôle secondaire en comparaison de l'indice synthétique de fécondité, et ne font donc l'objet que d'un bref exposé.

L'analyse, transversale et longitudinale, révèle que le mariage et les naissances ont eu tendance à survenir à un âge plus précoce. Comme on le voit au tableau 4.2, l'âge moyen à l'accouchement a diminué progressivement passant de 30 ans en 1930 à 27.0 ans en 1971, et l'âge modal est tombé de presque 28 ans à 23.3 ans. Cette tendance à constituer sa famille à un âge plus précoce a été un important facteur de l'explosion démographique de l'après-guerre qui s'est poursuivie jusqu'en 1960. Non seulement les gens se mariaient plus jeunes mais encore les intervalles entre les naissances étaient de plus en plus courts.

La situation concernant le calendrier des naissances ces dernières années est assez difficile à interpréter. D'une part, les données du moment des années 60 indiquent un ralentissement de la baisse de l'âge à l'accouchement, particulièrement apparent dans la tendance récente de l'âge modal. D'autre part, les données longitudinales, malheureusement toujours fragmentaires, indiquent non seulement un ralentissement mais encore un renversement de tendance. L'âge moyen au premier et au second enfant a légèrement augmenté dans les générations nées dans la première moitié des années 40 (femmes en âge de procréer dans les années 60), et l'intervalle moyen entre le mariage et le premier enfant et entre le premier et le deuxième enfant semble lui aussi s'être allongé<sup>15</sup>. Aux États-Unis on a observé une évolution analogue dans l'échelonnement des naissances et dans le processus de formation de la famille.

Différentes raisons expliquent cette tendance (réelle ou apparente) à édifier sa famille à un âge plus avancé. Il semble que l'accès à des méthodes contraceptives plus efficaces ait eu pour effet de retarder les mariages et les naissances, en permettant d'éviter un certain nombre de grossesses "non désirées" qui se seraient produites en d'autres temps. Le déséquilibre des effectifs mariables (c'est-à-dire la disproportion entre le nombre de femmes et d'hommes en âge de se marier) a contribué à la réduction du taux de nuptialité observée parmi les jeunes générations<sup>16</sup>. D'autres causes d'ordre économique ont pu contribuer à l'ajournement du processus de formation de

more difficult access to job opportunities experienced by young people in recent years.<sup>17</sup>

In the above context, it is tempting to postulate alternative assumptions, i.e., one implying an older and another a younger age pattern of fertility. Unfortunately, in doing this one would end up with an unmanageable number of possible combinations of assumptions regarding total fertility rate (three), mean age (two), and mode age (two). In order to avoid this, a single assumption, a moderate decline in the mean and mode age of fertility up to the mid-eighties, has been retained, as shown in Table 4.2.

It was felt that some of the factors alledged to have caused the age of childbearing among younger cohorts to increase slightly are temporary phenomena, such as the "marriage squeeze". Thus, it is considered that the social climate, as well as the psychological attitudes favouring early family formation, are likely to prevail in the society.

### Provincial Fertility Projections

Fertility parameters used to project births by provinces were derived from corresponding parameters projected for Canada by applying what may be termed the "ratio" method. According to this method, ratios of provincial to national values, for a given parameter, were calculated and projected forward.<sup>18</sup> Values of provincial parameters for the future years were then obtained by applying the projected ratios to the corresponding national parameters which were projected in accordance with the methods explained in the preceding section. It should be pointed out that the ratio method was applied to all provinces except Prince Edward Island, Newfoundland, Yukon and Northwest Territories. For reasons to be explained later, these areas were treated differently.

The decision to adopt the "ratio" method was reached after a careful study of the patterns of

la famille: par ex., les difficultés d'emploi rencontrées par les jeunes au cours des dernières années<sup>17</sup>.

En face de ces constatations, on est tenté d'avancer deux hypothèses tout à fait opposées, l'une supposant un âge de fécondité plus jeune, l'autre plus âgé. Mais, ce faisant, nous en arriverions à un nombre de combinaisons d'hypothèses pour le moins difficile à manipuler concernant l'indice synthétique de fécondité (trois), l'âge moyen (deux), et l'âge modal (deux). Pour éviter cela, nous avons décidé de n'utiliser qu'une hypothèse, soit une baisse modérée de l'âge moyen et de l'âge modal à l'accouchement jusqu'au milieu des années 80, comme le montre le tableau 4.2.

Nous avons estimé que certains des facteurs auxquels on attribue la légère hausse de l'âge à l'accouchement parmi les jeunes générations ne sont que temporelles, par exemple le déséquilibre des effectifs mariables. Nous croyons donc que le climat social et les attitudes psychologiques favorables à la formation précoce de la famille demeureront des facteurs prépondérants dans notre société.

### Hypothèses de fécondité au niveau provincial

À partir des paramètres de fécondité utilisés dans les projections pour le Canada, on a obtenu les paramètres correspondants nécessaires aux projections de naissances par province, en appliquant ce qu'on pourrait appeler la méthode des rapports. Selon cette méthode, on a calculé, puis projeté<sup>18</sup>, les rapports province/Canada, pour un paramètre donné. En appliquant ces rapports aux paramètres correspondants au niveau national, projetés conformément aux méthodes expliquées dans la section précédente, on a ainsi obtenu les valeurs des paramètres au niveau provincial. Il convient de noter que la méthode des rapports a été appliquée à toutes les provinces à l'exception de l'Île-du-Prince-Édouard, de Terre-Neuve, du Yukon et des Territoires du Nord-Ouest lesquelles, pour des raisons qui seront expliquées plus loin, ont reçu un traitement différent.

Ce n'est qu'après étude attentive des variations interprovinciales des séries chronologiques tant au niveau

<sup>17</sup> R.A. Easterlin, "Towards a Socio-economic Theory of Fertility: A Survey of Recent Research on Economic Factors in American Fertility", in S.J. Behrman et al. (Eds.), *Fertility and Family Planning, A World View* (Ann Arbor: University of Michigan Press, 1969), pp. 127-156.

<sup>18</sup> In fact, projections by this method were first done by cohorts. The fertility parameters – total fertility and mean age of fertility – were then translated into period total fertility rates. Some adjustments were made to remove inconsistencies between observed values of total fertility rates and the ones derived from cohort fertility measures. For more detailed account of fertility projections for provinces see D. Vanasse-Duhamel, "Cohort Fertility in Eight Canadian Provinces", Working Paper (P.E.P. Series) No. 9E (Ottawa: Statistics Canada, October 1972).

<sup>17</sup> R.A. Easterlin, "Towards a Socio-economic Theory of Fertility: A Survey of Recent Research on Economic Factors in American Fertility", in *Fertility and Family Planning, A World View*, S.S. Behrman et al. (Eds.), Ann Arbor: University of Michigan Press, 1969, pp. 127-156.

<sup>18</sup> En réalité, on a d'abord fait des projections par génération. À l'aide des formules de translation, les paramètres de fécondité – descendance finale et âge moyen à l'accouchement – ont ensuite été transformés en indice synthétique de fécondité. On a effectué quelques corrections destinées à supprimer les écarts entre les valeurs observées de l'indice synthétique de fécondité et celles tirées des mesures de fécondité des générations. Pour plus de détails sur les projections de la fécondité au niveau provincial, consulter le document de travail de D. Vanasse-Duhamel "La fécondité des générations dans huit provinces canadiennes: analyse et projection" (Séries P.E.P.), n° 9F (Ottawa, Statistique Canada, octobre 1972).

<sup>1</sup> Figures are not available prior to 1956. — Les données ne sont pas disponibles avant 1956.

interprovincial variations in the time series of both cohort and period fertility parameters. More particularly, the study was aimed at revealing: (1) whether there are similarities between provinces with regard to fertility variations through time (2) what the respective ranking of each province is with regard to the level of a given parameter, and whether there is some consistency in the ranking over time, and (3) whether or not there is a tendency toward a convergency, that is, whether the gap between provinces with regard to a particular fertility parameter tends to become narrower or wider over time.

In the first instance, results of the study are quite conclusive. The time series reveals a consistent picture of the time variations the provinces underwent with regard to the total fertility rates, whether they are looked at longitudinally by cohort or cross-sectionally by period. All provinces experienced, although at different levels, similar high and low fertility cycles, and the returning points coincided closely in time for all of them (Table 4.3). Similarities between provinces are even greater with respect to time trends in the age patterns of fertility, as is shown in Table 4.4.

Data regarding the ranking of the provinces with respect to the period total fertility rate and the period age pattern of fertility are presented in Tables 4.5 and 4.6. Some provinces consistently experienced comparatively "high" fertility levels, whereas others consistently had comparatively "low" fertility levels. For example, British Columbia, Ontario, and to a lesser extent, Manitoba, have been traditionally "low" fertility provinces, and they have continued to rank

longitudinal que transversal qu'on a opté pour la méthode des rapports. Plus précisément, l'étude visait à vérifier: (1) si la fécondité des provinces a évolué de façon similaire au cours du temps; (2) quel est le rang de chaque province pour chaque paramètre de fécondité et s'il existe une continuité chronologique de ce rang; et (3) s'il existe ou non une tendance à la convergence, c'est-à-dire, si l'écart qui existe entre les provinces pour un paramètre donné de fécondité tend à diminuer ou à s'accentuer avec le temps.

On peut dire en tout premier lieu que les résultats de l'étude sont concluants. L'observation des séries chronologiques indique une étonnante similitude dans l'évolution de l'indice synthétique de fécondité des provinces, tant du point de vue longitudinal que transversal. Toutes les provinces, bien qu'à des niveaux différents, ont connu des cycles similaires de forte et de faible fécondité et des points d'inflexion qui coïncidaient presque exactement dans le temps (tableau 4.3). Les similitudes entre provinces sont encore plus sensibles en ce qui concerne l'évolution du calendrier (âge moyen de la fécondité), comme le montre le tableau 4.4.

Les données sur le classement des provinces d'après l'indice synthétique de fécondité et d'après l'âge moyen à l'accouchement sont présentées dans les tableaux 4.5 et 4.6. Certaines provinces ont continuellement connu des niveaux de fécondité comparativement "élevés" et d'autres des niveaux comparativement "faibles". Par exemple, la Colombie-Britannique, l'Ontario et, dans une moindre mesure, le Manitoba, ont toujours été des provinces de "faible" fécondité et elles ont occupé cette

among the lowest to the present time. In contrast, New Brunswick tops as the first ranking high fertility province, while Nova Scotia maintains a middle position throughout. Alberta, and especially Saskatchewan, shift gradually from "middle" to "high" fertility positions. However, the fertility evolution of Quebec is the most dramatic, since the rank of its total fertility rate has moved from the highest in Canada to the lowest in the last ten years or so.

Consistency in the ranking of provinces with respect to the age pattern of fertility through time is almost perfect. There is indeed very little shift in the ranking of the provinces when classified by the level of mean age of fertility (Table 4.6). For example, Quebec has always had the highest, whereas British Columbia, followed by Ontario, had the lowest mean age of fertility.

To test for convergency of the total fertility rate and the mean age of fertility, the standard deviation of provincial values of these parameters was calculated for five-year periods from 1926. It can be inferred from Table 4.7, that the tendency toward convergency is quite strong in the movement of the total fertility rates by provinces. A similar but less pronounced tendency is observed with regard to the mean age of fertility (Table 4.8).

Implicit in the projections of the provincial fertility parameters is the recognition of the durability of the three features that emerge from the aforesaid analysis. It is assumed that in all the provinces

position jusqu'à nos jours. Par opposition, le Nouveau-Brunswick s'est maintenu au premier rang, tandis que la Nouvelle-Écosse conservait une position moyenne. L'Alberta et, plus encore, la Saskatchewan sont passées graduellement des rangs "moyens" aux rangs "élevés". Quant à l'évolution de la fécondité du Québec, elle est la plus frappante: l'indice synthétique de fécondité de cette province, dans les dix dernières années ou à peu près, est passé du niveau le plus élevé au niveau le plus bas au Canada.

Le classement des provinces en ce qui concerne le calendrier de la fécondité présente une continuité presque parfaite à travers le temps. Si l'on classe les provinces selon l'âge moyen à l'accouchement il n'y a eu en fait que peu de changement dans le classement des provinces (tableau 4.6). Par exemple, le Québec a toujours été caractérisé par l'âge moyen de fécondité le plus élevé, tandis que la Colombie-Britannique et l'Ontario, avaient les niveaux les plus bas.

Afin de vérifier s'il existe une convergence de l'indice synthétique de fécondité et de l'âge moyen à l'accouchement entre les provinces, on a calculé l'écart-type des valeurs provinciales de ces paramètres par période de cinq ans à partir de 1926. Le tableau 4.7 montre que la tendance à la convergence est très forte dans l'évolution des niveaux de fécondité des provinces. On observe une tendance semblable, quoique moins accentuée, pour l'âge moyen à l'accouchement (tableau 4.8).

Dans les projections de la fécondité au niveau provincial on admet implicitement la permanence des trois caractéristiques tirées de l'analyse qui précède. On suppose que, dans toutes les provinces considérées, la

considered, fertility trends will continue to evolve in the same manner as the national fertility trends and that they will retain their rank of more recent years. It is further assumed that there will be a tendency toward convergency for total fertility rate and, though to a lesser extent, for mean age.

One major reason why our provincial projections were tied to the national projections (rather than preparing projections for each province independently)

fécondité poursuivra une évolution parallèle à celle de l'ensemble du pays et que les provinces garderont le rang qu'elles occupaient ces dernières années. On suppose également que la tendance à la convergence sera observée dans l'évolution de l'indice synthétique de fécondité et, dans une moindre mesure, dans celle de l'âge moyen à l'accouchement.

L'une des principales raisons pour lesquelles nous avons lié les projections provinciales aux projections nationales (plutôt que de calculer des projections pour

stems from the fact that data on fertility at the national level are more complete and afford a more thorough analysis. For example, in formulating the assumptions regarding the period total fertility rate, considerable reliance was placed on the analysis of data on cohort fertility by birth orders, for which relevant data are available for Canada but not for the provinces. However, it would be incorrect to assume that the provincial series did not play a significant role in the derivation of fertility assumptions for Canada. On the contrary, in accordance with our "regional approach"<sup>19</sup> the fertility series, especially for those which emerge as "leading" provinces with regard to the movement of a given parameter, provided some guidance in setting the possible future levels for national fertility parameters.

Special treatment was required in the case of Prince Edward Island, Yukon, Northwest Territories and Newfoundland. The first three have a very small population and their fertility indices behave in a rather erratic way. Furthermore, the available historical series are too short to offer an adequate time perspective for projection. On the other hand, Newfoundland does not have the required data on age-specific fertility rates, and consequently it was necessary to estimate its fertility parameters indirectly. For all these reasons, a more crude method of extrapolating future fertility was used. Fertility in these areas, especially in the Yukon and Northwest Territories, is still very high compared to the national level. It is assumed that fertility in the Northwest Territories will decline in the future, but that this region will continue to have the highest fertility levels in Canada.

chaque province isolément) est que les données de fécondité au niveau du Canada sont plus complètes et permettent une analyse plus approfondie. Par exemple, dans la formulation des hypothèses concernant l'indice synthétique de fécondité, on s'est largement fié à l'analyse de la fécondité des générations par rang de naissances, pour laquelle les données existaient au niveau du Canada seulement. Toutefois, il serait inexact d'en conclure que l'évolution de la fécondité au niveau provincial ne joue pas de rôle important dans la formulation des hypothèses de fécondité pour le Canada. Au contraire, conformément à notre "méthode régionale"<sup>19</sup>, l'observation de la fécondité dans les provinces, spécialement dans celles qui semblent être à l'avant-garde quant à l'évolution d'un paramètre donné, a fourni une certaine orientation dans l'établissement des niveaux futurs des paramètres de fécondité à l'échelle du Canada.

On a dû procéder différemment pour l'Île-du-Prince-Édouard, le Yukon et les Territoires du Nord-Ouest et Terre-Neuve. Les trois premières régions ont une très faible population et leurs indices de fécondité évoluent d'une manière assez irrégulière. De plus, les séries chronologiques disponibles sont trop courtes pour offrir une perspective suffisante pour des projections. Par ailleurs, on ne possède pas pour Terre-Neuve des données portant sur les taux de fécondité selon l'âge de la mère et il a donc été nécessaire d'estimer, par un calcul indirect, les paramètres de fécondité pour cette province. Pour toutes ces raisons, on a utilisé une méthode plus simple de projection de la fécondité future. La fécondité, dans ces régions, et plus spécialement au Yukon et dans les Territoires du Nord-Ouest, est très supérieure au niveau national. On suppose que la fécondité dans les Territoires du Nord-Ouest baîssera dans les années à venir mais que cette région continuera à présenter les plus hauts niveaux de fécondité au Canada.

## CHAPTER 5

### Migration Projections

In this approach to projections, migration<sup>1</sup> was considered under two categories: (a) international and (b) interprovincial. The distinction between these categories is that international migration, composed of immigrants and emigrants, denotes the movement of people across national boundaries, while interprovincial migration, comprised of in-migrants and out-migrants, is the movement of people across provincial limits.

### Methodology

Migration is the most unstable parameter of population projections because it is governed by a variety of economic, demographic, social and political factors. Under the present state of knowledge and existing migration data bases, two kinds of methodology could be used to prepare migration projections, namely, an analytical method or migration model. The analytical method rests upon examining historical data and extrapolating future trends from them. In contrast, migration models depend on observed relationships between population flows and socio-economic variables. However, the art implicit in projection models is still in its infancy, and therefore the analytical method is used here.

Within the framework of an analytical approach, a number of strategies can be applied to develop migration projections. In earlier projections,<sup>2</sup> the particular strategy used involved examining the range and tempo of migration in absolute numbers over the past decade and calculating the average migration over different lengths of time, such as three-year periods (short-term), five-year periods (census-term), and ten-year periods or more (long-term). On the basis of this analysis, several alternative assumptions concerning expected future levels of immigration and emigration separately were made. A similar strategy was adopted with respect to expected future levels of interprovincial migration.

<sup>1</sup> This chapter on migration projections is based on the background paper by J. Perreault and K.S. Gnanasekaran, *International and Interprovincial Migration Projections: Canada and Provinces, 1951-1986* (Ottawa: Statistics Canada, 1973). (Background Paper.)

## CHAPITRE 5

### Projection de la migration

Pour établir ces projections on a divisé la migration<sup>1</sup> en deux catégories: (a) internationale et (b) interprovinciale. La distinction entre ces catégories est la suivante: la migration internationale, qui est composée d'immigrants et d'émigrants, représente le mouvement de personnes entre pays, tandis que la migration interprovinciale, qui est composée d'"entrants" et de "sortants", est le mouvement de personnes d'une province à l'autre.

### Méthodologie

Régie par un ensemble de facteurs socio-économiques, démographiques et politiques, la migration est la composante qui, dans l'établissement des projections, est le plus susceptible de fluctuer. Dans l'état actuel des connaissances et d'après les données disponibles, on pourrait avoir recours à deux méthodes différentes pour établir les projections de migration, soit la méthode analytique ou les modèles de migration. La méthode analytique s'appuie sur l'examen de données chronologiques et l'extrapolation des tendances futures à partir de ces données. Par contre, les modèles de migration sont construits en fonction des rapports observés entre les mouvements migratoires et les variables socio-économiques. Comme la technique utilisée dans les modèles de projection n'est encore qu'à l'état embryonnaire on a eu recours ici à la méthode analytique.

Dans le cadre de la méthode analytique, diverses approches peuvent être envisagées. Dans les projections antérieures<sup>2</sup>, on examinait l'éventail et le rythme de la migration, en chiffres absolus, au cours de la dernière décennie et l'on calculait des moyennes sur différentes périodes, par exemple trois ans (à court terme), cinq ans (recensement), et dix ans ou plus (à long terme). À partir de cette analyse, plusieurs hypothèses concernant les niveaux prévus d'immigration et d'émigration ont été formulées. Une méthode semblable a été adoptée pour la projection de la migration interprovinciale.

<sup>1</sup>Ce chapitre est fondé sur l'étude préliminaire préparée par J. Perreault et K.S. Gnanasekaran, *International and Interprovincial Migration Projections: Canada and Provinces, 1951-1986* (Ottawa: Statistique Canada), 1973. (Document non publié.)

Gnanasekaran, *Population and Labour Force Projections for Alberta, 1970-1985* (Edmonton: Human Resources Research Council, 1972) pages 102 à 115.

## International Migration

Historically, international migration has been and continues to be an important source of population change in Canada and the provinces. The post World War II years witnessed a consistent gain through external migration, in contrast to the pattern of both net gains and losses in some decades in the pre-war period. The migration contribution during 1961-1971 amounted to one fifth of the population increase in the same period.

A comprehensive analysis of immigration and emigration was carried out for the 1969 population projections.<sup>3</sup> Most of the findings and assumptions in this study hold good even now and hence are adopted for use in the present projections. According to this study, the average for the three years with the greatest amount of immigration during the 1960's was found to be 200,000 a year. Likewise, the average for the three years of very low immigration was approximately 80,000 persons per annum. Immigration trends since 1969 have not altered this range, and consequently immigration levels in the present projections are also assumed to range between 80,000 and 200,000 a year in future.

**TABLE 5.1. Assumed Average Annual Immigration and Emigration, 1972 - 1986**

**TABLEAU 5.1. Hypothèses de migration internationale: nombre annuel moyen d'immigrants et d'émigrants, 1972 - 1986**

	Gross immigration Immigration	Gross emigration Émigration	Net immigration Migration nette	
			thousands — en milliers	
Assumption — 0 — Hypothèse .....	0	0		0
" 1 " .....	200	60		140
" 2 " .....	160	60		100
" 3 " .....	120	60		60
" 4 " .....	80	60		20

The average emigration over the post-war period varied from 64,000 a year when immigration was high to 60,000 a year when immigration was low. Estimates showed a decline in emigration after 1969, but it is difficult to judge whether this is a temporary or permanent phenomenon, and therefore the previous assumption of 60,000 emigrants a year was retained in the present set of projections.

Chart 5.1 illustrates the trends in international migration during the post-war period and it may be

## Migration internationale

La migration internationale a toujours été et continue à être un facteur important de la croissance de la population du Canada et des provinces. Dans les années qui suivirent la deuxième guerre mondiale, la population s'est accrue constamment grâce à la migration étrangère, contrairement à certaines décennies avant la guerre. Le solde migratoire de 1961 à 1971 représentait un cinquième de l'accroissement démographique total.

Une analyse approfondie de l'immigration et de l'émigration a été effectuée en 1969 par Statistique Canada pour ses projections de population<sup>3</sup>. La plupart des hypothèses avancées et des résultats obtenus sont encore valides aujourd'hui et ont donc été retenus pour les présentes projections. D'après cette étude, la moyenne des trois années où l'immigration a été la plus forte durant les années 60 s'est élevée à 200,000 immigrants par année. De même, la moyenne des trois années où l'immigration a été la plus faible a été d'environ 80,000 personnes par an. Comme depuis 1969, l'immigration s'est maintenue à l'intérieur de ces limites, on a supposé que dans l'avenir les niveaux d'immigration se situeront entre 80,000 et 200,000 par an.

Au cours de la période d'après-guerre, l'émigration moyenne a varié entre 64,000 par an, lorsque l'immigration était à son plus haut niveau et 60,000 par an lorsque l'immigration était à son plus bas. Les estimations récentes indiquent une diminution après 1969, mais il est difficile de savoir s'il s'agit simplement d'un phénomène passager; aussi on a décidé de retenir l'hypothèse précédente de 60,000 émigrants par an.

Le graphique 5.1 montre l'évolution de la migration internationale depuis 1946. Contrairement à l'immigra-

### Immigration To and Emigration From Canada, 1946-1986

#### Immigration et émigration, Canada, 1946-1986

Sources: Immigrants — Canada, Department of Manpower and Immigration, Immigration Statistics, 1946 to 1972, Immigration Division, DMI, Ottawa.  
 Emigrants — Estimates prepared in the Population Estimates and Projections Division, Statistics Canada, Ottawa.

Sources: Immigrants — Canada, Ministère de la Main d'Oeuvre et de l'Immigration, Statistiques de l'Immigration, 1946 à 1972, Divison de l'Immigration.  
 Émigrants — Estimations préparées par la division des Estimations et Projections démographiques, Statistique Canada, Ottawa.

noted that whereas immigration streams have been quite volatile and have fluctuated widely, emigration has varied within a comparatively small range. For this reason, four immigration assumptions within the range of 80,000 to 200,000 a year were postulated in this study. These assumptions are 200,000; 160,000; 120,000 and 80,000 immigrants a year. In contrast, a single assumption of 60,000 emigrants per annum was made here through 2001, as shown in Table 5.1. From recent experiences, the two assumptions of 160,000 and 120,000 immigrants per annum seem more probable and are therefore preferred later in this report. Moreover, in order to facilitate empirical analysis, hypothetical assumptions of zero immigration and zero emigration (i.e., Assumption 0) were also included in these projections.

The significance of immigration and emigration for population changes in the provinces can hardly be overstated. The distribution of immigrants to and emigrants from each province differed markedly from that of the total initial population. Thus, more than one-half of the total number of immigrants during 1961-1971 moved to Ontario. Only one other province, British Columbia, attracted a proportion of immigrants greater than its share of Canada's total population. Each of the remaining provinces received less than its proportionate share of Canada's population.

tion, caractérisée par une forte variabilité, le niveau de l'émigration a peu varié. Pour cette raison, on a donc formulé quatre hypothèses d'immigration, dans les limites observées: 200,000, 160,000, 120,000 et 80,000 immigrants par an. Par contre, une seule hypothèse, celle de 60,000 émigrants par an, a été retenue jusqu'en 2001, comme on peut le voir au tableau 5.1. Si l'on se base sur les observations récentes, les deux niveaux de 160,000 et 120,000 immigrants par an semblent les plus probables et on les a préférés aux autres dans la présente étude. De plus, pour faciliter l'analyse des résultats d'un point de vue empirique, une projection de population sans migration (hypothèse 0) a été incluse.

On peut difficilement exagérer le rôle joué par l'immigration et l'émigration dans l'évolution démographique des provinces. La répartition des immigrants et des émigrants dans chaque province diffère sensiblement de la proportion de chaque province dans la population totale. Ainsi, plus de la moitié du nombre total d'immigrants arrivés au Canada entre 1961 et 1971 se sont installés en Ontario. La Colombie-Britannique est la seule autre province à avoir attiré une proportion d'immigrants plus grande que sa part dans la population de l'ensemble du pays.

In contrast, emigration presented a different picture. The proportion of emigrants from Quebec, Ontario and New Brunswick exceeded their respective share of Canada's population while the opposite was true of other provinces. This pattern of distribution of emigrants/immigrants remained relatively consistent throughout the post-war period, and therefore the average percentage distribution of immigrants and emigrants by provinces during the three years 1968 to 1971 was assumed in Table 5.2 throughout the projection period.<sup>4</sup>

### Interprovincial Migration

One is faced with a variety of data problems in dealing with interprovincial migration. Ideally, a projection programme requires flow statistics vis-à-vis stock data. Historical estimates of interprovincial migration are generally based on the place of birth and/or place of residence data collected in the censuses. These may also be obtained indirectly by using the Vital Statistics Method or the Census Survival Ratio Method. Apart from several limitations and conflicts in such estimates derived from these different techniques, these estimates are essentially stock data and hence are not best suited for projections purposes.

En ce qui concerne l'émigration, on observe une situation différente. La proportion des émigrants quittant le Québec, l'Alberta et le Nouveau-Brunswick, a dépassé la part de ces provinces dans la population de l'ensemble du Canada alors que le contraire est vrai pour les autres provinces. Comme cette répartition des émigrants/immigrants s'est maintenue de façon relativement constante jusqu'à maintenant, nous avons donc adopté la répartition moyenne des immigrants et des émigrants par province pour la période 1968-1971, comme répartition-type pendant toute la période de projection<sup>4</sup>.

### Migration interprovinciale

En abordant l'étude de la migration interprovinciale, on se trouve confronté à une série de problèmes concernant les données. Idéalement, la projection devrait s'appuyer sur des statistiques du mouvement de la population comparées aux statistiques de l'état de la population. En général, les estimations des mouvements migratoires interprovinciaux sont fondées sur les données sur le lieu de naissance et (ou) de résidence, information recueillie lors des recensements. Il est également possible de mesurer indirectement les mouvements migratoires en utilisant les données de l'état civil ou encore par la méthode des probabilités de survie. Outre les lacunes nombreuses et le manque de comparabilité des estimations faites à partir de ces techniques, ces estimations ne constituent pas, essentiellement, des données de flux migratoire, elles ne satisfont donc pas entièrement aux besoins des projections.

<sup>4</sup> For details see J. Perreault and K.S. Gnanasekaran, *op. cit.*, pp. 13-16.

<sup>4</sup> Consulter le document de J. Perreault et K.S. Gnanasekaran, *op. cit.*, pages 13 à 16.

For the present set of projections, interprovincial migration estimates obtained from the family allowances data were utilized,<sup>5</sup> as by and large they correspond to flow statistics. Methodologically, it was considered preferable to project in- and out-migration rather than net migration only, and hence new data series of in- and out-migration for 1961-1971 for projections purpose were developed for each province and territory from the family allowance data.<sup>6</sup>

Estimates of interprovincial migration by Kasahara indicated a gross movement (i.e., in- or out-migration) of 371,000 a year during 1951-1956, and of 412,000 during 1956-1961.<sup>7</sup> Of this interprovincial movement, about 30% constituted in-migration to Ontario. British Columbia, Alberta, and Quebec followed Ontario as areas of attraction of in-migrants, dividing among them another 40% of the total inflow. Although, among other factors, industrial expansion and economic conditions in these provinces attracted a large volume of migration from outside, each of them also constituted an important supply area of migrants for other provinces. Over 20% of the total out-migrants each year originated from Ontario, while Quebec, Alberta and British Columbia accounted for 38% of the total outflow. Because of the larger inflow of people, the balance of in- and out-migration remained positive for Ontario, British Columbia and Alberta. Quebec, on the other hand, experienced a net interprovincial migration loss throughout the entire ten-year period. Similarly, Newfoundland, Prince Edward Island, Nova Scotia, New Brunswick, Manitoba and Saskatchewan lost consistently during these two intercensal periods. The Yukon and Northwest Territories both gained and lost population as a result of migratory movements, but, on balance, they gained in this period.

The gross and net movements of population during the last decade shown in Table 5.3 disclosed three aspects. First, the gross in- or out-migration averaged 375,000 during 1961-1966, and this is slightly less than the volume attained during 1956-1961. This small drop was also noticed in terms of net migration considered irrespective of sign, since the net interprovincial migration is always zero at the national level. In the 1966-1971 period, the average amounted to 435,000 a year, implying a rise in volume compared to the preceding quinquennium. Over the entire four

<sup>5</sup> For details, see Yoshiko Kasahara, "The Flow of Migration among the Provinces in Canada, 1951-1961", in Canadian Political Science Association, *Conference on Statistics* 1961 (Toronto: University of Toronto Press, 1963) pp. 20-25.

<sup>6</sup> See J. Perreault and K.S. Gnanasekaran, *op. cit.*, pp. 44-54.

<sup>7</sup> Yoshiko Kasahara, *op. cit.*, pp. 35-36.

Dans les présentes projections, on a eu recours aux estimations de migration interprovinciale faites à partir des données sur les allocations familiales<sup>5</sup> car elles correspondent dans une large mesure aux statistiques de flux migratoire. Sur le plan méthodologique, on a cru préférable de considérer séparément les "entrées" et les "sorties" plutôt que le solde migratoire. On a donc estimé pour chaque province et territoire le nombre des "entrées" et des "sortants" pour chacune des années entre 1961 et 1971, à partir des données sur les allocations familiales<sup>6</sup>.

Les estimations de la migration interprovinciale établies par Y. Kasahara ont mis en évidence un niveau de mobilité ("entrées" et "sorties") de 371,000 personnes par an de 1951 à 1956 et de 412,000 de 1956 à 1961.<sup>7</sup> De ce nombre, environ 30 % se sont installés en Ontario. Après l'Ontario, c'est la Colombie-Britannique, l'Alberta et le Québec qui ont attiré le plus grand nombre de migrants, ces provinces ayant reçu près de 40 % du total des migrants. Entre autres facteurs, l'expansion industrielle et la situation économique de ces provinces ont attiré un nombre considérable de migrants. Chacune d'elles a également constitué une importante source de migrants pour les autres provinces. Plus de 20 % des "sorties" proviennent de l'Ontario, alors que les sorties du Québec, de l'Alberta et de la Colombie-Britannique vers d'autres provinces ont représenté 38 % du nombre total des "sorties". Étant donné le niveau plus élevé des "entrées" que des "sorties", le solde migratoire a généralement favorisé l'Ontario, la Colombie-Britannique et l'Alberta. Par contre, le Québec a connu un solde migratoire interprovincial négatif tout au long de la décennie considérée. De même, la migration nette à Terre-Neuve, à l'Île-du-Prince-Édouard, en Nouvelle-Écosse, au Nouveau-Brunswick, au Manitoba et en Saskatchewan a été constamment négative. Quant au Yukon et aux Territoires du Nord-Ouest, les mouvements migratoires nets ont été parfois positifs, parfois négatifs, mais dans l'ensemble, le solde migratoire leur a été favorable.

Trois aspects particuliers retiennent l'attention lorsque l'on examine les mouvements de la population au cours de la dernière décennie (tableau 5.3). Premièrement le nombre annuel d'entrées-sorties a atteint en moyenne 375,000 de 1961 à 1966, soit un peu moins que celui observé de 1956 à 1961. Cette légère baisse s'est également manifestée dans le solde migratoire considéré indépendamment du signe, puisque le solde migratoire interprovincial est par définition égal à zéro au niveau national. Durant la période de 1966 à 1971, le niveau de mobilité moyen a été de 435,000 par an, ce qui représente une

intercensal periods from 1951-1971, it may be concluded that the in-, out- and net migration among the provinces and territories showed no consistent upward or downward trend. Rather, the volume fluctuated between 371,000 and 435,000 a year or, in terms of net migration, between 33,000 and 59,000 per year.

augmentation par rapport à la période quinquennale précédente. Pour l'ensemble des quatre périodes intercensitaires allant de 1951 à 1971, les entrées, les sorties et le solde migratoire dans les provinces et territoires n'ont suivi aucune tendance systématique à la hausse ou à la baisse. Plutôt, le volume a fluctué entre 371,000 et 435,000 par an, ou, en termes de solde migratoire, de 33,000 à 59,000 par an.

Secondly, the pattern of migration — i.e., the gaining or losing provinces — remained remarkably the same in each intercensal period during 1951-1961. In contrast to this pattern, the net migration during

Deuxièmement, la répartition entre provinces "gagnantes" et provinces "perdantes" est demeurée pratiquement la même durant chaque période intercensitaire de 1951 à 1961. Contrastant avec ce schéma, le solde

1961-1966 turned positive for Quebec and negative for Alberta, Yukon and the Northwest Territories. However, during the subsequent and more recent intercensal period, 1966-1971, there was a return to the pattern of the 1950's, or to what by and large appears to be the "long-term" pattern, which may be described to include Ontario, British Columbia, Alberta, Yukon and the Northwest Territories as gaining areas, and the remaining as the losing provinces. Although fluctuations during this period in economic conditions had accentuated or diminished the volume of in-, out-, and net migration, it seems reasonable to assume that the foregoing pattern will continue in the future.

A third aspect of migration trends during this period relates to the combined effect of the volume of migration (gross in- and out-) and to its pattern of distribution on the net balance for each province, and in turn, to whether net migration was positive or negative. This aspect was particularly noticeable in the analytical method when the phenomenon was examined for a different period of time. Table 5.3, which presents the average gross and net movements of population within Canada in 1968-1969, 1969-1970 and 1970-1971, showed a gross in- or out-migration of 435,000 a year, a level which closely approximates that observed for the five-year period 1966-1971. However, due to differences in the percentage of share (i.e., pattern) of in- and out-migrants by provinces, the positive (or negative) net migration averaged 71,000 a year during the three-year period 1968-1971 as compared to 59,000 a year during the five-year period 1966-1971. Of course, from the standpoint of projections, the volume of net migration directly affects the projected size of population, and the gross in- and out-migration data play a significant role in the structure of the projected population size. Consequently, this important aspect must be borne in mind, as will be seen later, when the assumptions regarding future interprovincial migration levels are formulated.

Several factors, the most important of which are economic, have been suggested as being responsible for the foregoing trends and patterns in interprovincial migration. One explanation is that the provinces with the highest levels of per capita income, wages, or employment rate experience a net migration gain. No generalized economic and/or demographic model is readily available for the present projections. It is contended that demographic and non-demographic factors which would be at least partly responsible for future trends are reflected in past trends. Therefore, it is postulated here that future trends in interprovincial migration will not differ greatly from those of the recent past; however, in some provinces and/or periods efforts may be made which to some extent could modify the past trends. These efforts represent new policies whose precise effects on population movements are difficult to foresee. In the context, the following five assumptions are put forward with a view

migratoire de 1961 à 1966 est devenu positif au Québec et négatif en Alberta, au Yukon et dans les Territoires du Nord-Ouest. Toutefois, durant la période suivante et la plus récente (1966-1971), on est revenu à la répartition des années 50, ce qui permet de considérer l'Ontario, la Colombie-Britannique, l'Alberta, le Yukon et les Territoires du Nord-Ouest comme provinces traditionnellement "gagnantes" et les autres comme "perdantes". Bien qu'au cours de cette période les fluctuations des conditions économiques aient accentué ou atténué le niveau de la mobilité interprovinciale, il semble raisonnable de penser que la même répartition se maintiendra dans l'avenir.

Un troisième aspect de l'évolution de la migration au cours de cette période concerne l'effet combiné du niveau de la mobilité (le nombre d'entrées et de sorties) et de la migration nette propre à chaque province, et du sens du solde migratoire (positif ou négatif). La méthode analytique a particulièrement mis cet aspect en évidence, en permettant l'analyse sur des périodes différentes. Le tableau 5.3 présente la moyenne des mouvements migratoires à l'intérieur du Canada en 1968-69, 1969-70 et 1970-71. Pendant cette période le niveau moyen de mobilité était de 435,000 par an, niveau très proche de celui observé pour la période quinquennale de 1966 à 1971. Cependant, à cause d'un schéma de répartition entre provinces différent selon la période considérée, le solde migratoire, abstraction faite du signe, a atteint en moyenne 71,000 par an durant la période de trois ans de 1968-71 comparativement à 59,000 par an durant la période quinquennale de 1966-71. Il est évident que, du point de vue des projections, c'est le niveau de migration nette qui influe directement sur la taille de la population; quant aux données d'entrées et de sorties, elles jouent un rôle important dans la répartition selon l'âge et le sexe de la population future. En conséquence, il ne faudra donc pas oublier cet aspect important lors de la formulation des hypothèses de migration interprovinciale.

Plusieurs facteurs, dont les plus importants sont d'ordre économique, ont été invoqués pour expliquer l'évolution de la migration interprovinciale, entre autres le fait que les provinces où le revenu per capita, les rémunérations et le niveau de l'emploi sont les plus élevés, connaissent un solde migratoire positif. On ne dispose, pour établir ces projections, d'aucun modèle économique et (ou) démographique taillé sur mesure. On se contente d'admettre que les facteurs démographiques et non démographiques qui pourraient, du moins en partie, influer sur les tendances futures, se retrouvent dans les tendances passées. On part donc de l'hypothèse que l'évolution future de la migration interprovinciale ne sera pas tellement différente de celle des dernières années. Toutefois, dans certaines provinces et (ou) à certaines périodes, il se peut que des efforts soient déployés en vue de modifier dans une certaine mesure les tendances précédentes. Ce pourrait être, par exemple, de nouvelles politiques dont les effets précis sur les mouvements

to depict the future demographic situation under a range of likely courses of migration.

**Assumption 0** — In line with a similar assumption earlier concerning international migration, it is postulated here that in- and out-migration will in future be zero for each province and territory. Of course, this is merely a hypothetical assumption and is proposed to facilitate empirical studies.

**Assumption A** — Here, the hypothesis is that the average pattern of interprovincial migration observed during the 1968-69 through 1970-71 period will continue in the future. As shown in Table 5.4, the level of gross in- or out-migration, however, is assumed at 450,000 a year throughout the projection period, or a net positive (or negative) migration of 73,000 per annum, compared to the observed average values of 435,000 and 71,000 a year respectively during this three-year period. Assumption A is thus intended to allow for a small increase in the absolute level, while the rate will by and large remain constant during at least the short term.

<sup>1</sup> Assumption C which is not shown in the table equals one half of the in-and out-migration figures shown under Assumption B for each province and territory. — L'hypothèse C correspond, pour chaque province et territoire, à la moitié du nombre des entrées et des sorties de l'hypothèse B.

Sources: Table 5.3 and see text. Also J. Perreault and K.S. Gnanasekaran, *op. cit.*, pp. 28 and 31. — Tableau 5.3 et consulter le texte. Également J. Perreault et K.S. Gnanasekaran, *op. cit.*, p. 28 et p. 31.

**Assumption B** — Instead of a three-year average as in the foregoing assumption, here it is supposed that future interprovincial migration patterns will resemble the average pattern experienced during the 1966-67 to 1970-71 five-year period. This assumption implies a gross in- or out-migration of 435,000 or a net positive (or negative) migration of about 59,000 a year as shown in Table 5.4.

**Assumption C** — On the basis of an examination of past trends in interprovincial migration of the

migratoires sont difficiles à prévoir. En conséquence, on a choisi les cinq hypothèses suivantes comme étant les plus susceptibles de représenter la situation future.

**Hypothèse O** — Comme on l'a fait précédemment pour la migration internationale, on suppose ici qu'il n'y aura aucun mouvement de population entre les provinces ou territoires. C'est, de nos jours, une hypothèse fort peu vraisemblable et elle est proposée surtout pour faciliter l'analyse des résultats.

**Hypothèse A** — On pose ici comme hypothèse que la répartition moyenne de la migration interprovinciale observée de 1968-69 à 1970-71 se maintiendra dans l'avenir. Comme on le voit au tableau 5.4, on suppose que le niveau de la mobilité sera de 450,000 par an durant toute la période de projection, soit un solde migratoire de ± 73,000 par an, comparativement aux moyennes estimées de 435,000 et de ± 71,000 par an, respectivement, pendant cette même période de trois ans. L'hypothèse A vise donc à prévoir le cas d'une faible augmentation, en chiffres absolus, alors que le taux, pour sa part, se maintiendrait à un niveau constant, à court terme du moins.

**Hypothèse B** — Au lieu d'une moyenne de trois ans comme dans l'hypothèse précédente, on suppose ici que la répartition de la migration interprovinciale suivra de près celle observée durant la période quinquennale de 1966-67 à 1970-71. Cette hypothèse implique un niveau de mobilité annuel de 435,000 ou un solde migratoire d'environ ± 59,000 par an (voir tableau 5.4).

**Hypothèse C** — Si l'on examine l'évolution de la migration interprovinciale de la population née au

Canadian-born population, it can be inferred that between 1931 and 1961 the attractive power of the (migration) gaining provinces upon the losing provinces has gradually diminished during these decades.<sup>8</sup> Further, in considering the range of future possibilities, it is considered likely that employment opportunities and other social and economic differentials among the provinces, which have been widely held as being responsible for past and present migratory propensities, may tend to narrow down over the years. Consequently, it is postulated here that net migration of provinces will be one-half the level experienced during 1966-1971. This assumption will mean a net positive (or negative) interprovincial migration of about 29,000 a year over the projection period (Table 5.4).

**Assumption D** — Like the preceding assumption, this is also offered specifically on the basis that economic opportunities will improve in the losing provinces. It differs, however, from the previous assumption in that the assumed levels and patterns are inferred from past trends. Table 5.4 presents the average volume of migration for the losing provinces in three "good" years and for the gaining provinces in three "bad" years during the decade 1961-1971. A "good" year is here defined as one in which a province lost fewer people or even gained people through net migration. Likewise, a "bad" year for a province is one in which they attracted fewer people or even lost some through net migration. Since the "good" or "bad" years differed for each province, the net migration would not add up to zero at the national level. Therefore, the figures for the losing provinces in 1961-1971 were added to yield what is known as "the out-migration basket". This "basket" was proportionately distributed among the gaining provinces according to the volume of average migration during their three "bad" years. The implied level of migration under Assumption D will be  $\pm 22,000$  a year and its pattern is shown in Table 5.4.

#### Assumed Migration Projections Series

The foregoing analyses and assumptions regarding international and internal migration still leave an important question unanswered for preparing migration projections for Canada and the provinces. The issue concerns the interrelationships between international and interprovincial migration in Canada. Inference, on the basis of past trends, is that international and internal migration do not appear to compete with each other; rather, the two tend to move in the same direction depending chiefly on the state of economy.

<sup>8</sup> M.V. George, *Internal Migration in Canada: Demographic Analyses* (Ottawa: Queen's Printer, 1970) p. 108.

Canada, on constate qu'entre 1931 et 1961 la force d'attraction des provinces "gagnantes" s'est progressivement atténuée au cours des dernières décennies<sup>8</sup>. De plus, si l'on analyse l'éventail des possibilités futures, il est possible que l'écart entre les provinces en ce qui concerne les possibilités d'emploi et la situation socio-économique en général, écart tenu en grande partie responsable des mouvements migratoires passés et présents, ait tendance à diminuer au cours des années. Par conséquent, on pose l'hypothèse que le solde migratoire représentera la moitié de celui qui a été estimé en 1966-1971. Cette hypothèse se traduira par un solde migratoire interprovincial d'environ  $\pm 29,000$  par an tout au long de la période de projection (voir tableau 5.4).

**Hypothèse D** — Comme l'hypothèse précédente, celle-ci est essentiellement fondée sur l'idée que les conditions économiques pourraient éventuellement s'améliorer dans les provinces traditionnellement perdantes. Elle diffère cependant de l'hypothèse précédente en ce sens que le niveau de mobilité prévu et sa répartition par province sont déduits des tendances passées. Le tableau 5.4 présente le volume moyen de migration dans les provinces "perdantes" durant trois "bonnes" années et dans les provinces "gagnantes" durant trois "mauvaises" années de la décennie 1961-1971. On entend par "bonne" année une année où les provinces perdent peu de gens ou même enregistrent un solde migratoire positif. De même, une "mauvaise" année est celle durant laquelle les provinces ont attiré moins de gens ou même ont enregistré un solde migratoire négatif. Puisque les années "bonnes" ou "mauvaises" diffèrent selon les provinces, le solde migratoire à l'échelle nationale n'aboutira pas à zéro. En conséquence, on a additionné les données concernant les provinces traditionnellement "perdantes" pour produire ce qu'il est convenu d'appeler "la somme des sorties". Cette valeur a été répartie de façon proportionnelle entre les provinces "gagnantes" en se basant sur la migration moyenne des trois "mauvaises" années. Le solde migratoire selon l'hypothèse D sera de  $\pm 22,000$  par an et sa répartition par province figure au tableau 5.4.

#### Relation entre les migrations internationale et interprovinciale

L'analyse précédente laisse sans réponse une question importante pour les projections de migration au Canada et dans les provinces, à savoir la nature des liens qui existent entre les migrations internationale et interprovinciale au Canada. L'observation des tendances passées nous amène à constater que les migrations internationale et interne ne semblent pas se faire concurrence l'une l'autre; elles évoluent plutôt toutes deux dans le même sens selon la situation sur le plan économique.

<sup>8</sup> M. V. George, *Internal Migration in Canada: Demographic Analysis*, (Ottawa: Imprimeur de la Reine), 1970, page 108.

This relationship is applied here in integrating the international and internal migration assumptions postulated above and the following six series<sup>9</sup> are selected for combination with fertility and mortality projections (Tables 5.5 and 5.6).

C'est cette observation qui a servi de base ici à la combinaison des hypothèses de migrations externe et interne avancées ci-dessus. On a donc retenu les six combinaisons suivantes<sup>9</sup> pour les associer aux hypothèses de fécondité et de mortalité (tableaux 5.5 et 5.6).

#### Age-sex Composition of Migrants

The migration assumptions set forth in Table 5.6 are in aggregate terms. However, projections are frequently required in detail by age and sex. For this purpose, the age-sex composition of immigrants, emi-

#### Répartition des migrants selon l'âge et le sexe

Les hypothèses avancées au tableau 5.6 présentent le nombre total de migrants. Toutefois, on a souvent besoin de projections détaillées selon l'âge et le sexe. À cette fin, la répartition selon l'âge et le sexe des

<sup>9</sup> Barring the zero migration assumption, the combination of four international (Assumptions 1, 2, 3 and 4) and four interprovincial (Assumptions A, B, C and D) hypotheses will lead to sixteen series of migration projections.

<sup>9</sup> Si on exclut l'hypothèse de migration zéro, en combinant les quatre hypothèses de migration internationale (1, 2, 3, et 4) et les quatre hypothèses de migration interprovinciale (A, B, C, D) on obtiendrait seize projections de migration.

grants, in-migrants and out-migrants during a single year can be taken as the basis used to distribute the assumed total migration under different hypotheses. The composition of migrants is generally subject to variations annually, and therefore it is common practice to take average pattern over a period of three, five or ten years. A similar procedure was followed in the previous projections with respect to the age-sex structure of immigrants and emigrants, and, for the present projections, the average age-sex distributions of immigrants and emigrants<sup>10</sup> utilized in the previous set of projections were adopted throughout the projection period.

For the age-sex composition of in- and out-migration, a similar approach was used and the average age-sex composition of migrants for the three-year period from 1968-69 to 1970-71 was applied to the projected migration streams for each province and territory.<sup>11</sup>

immigrants, émigrants, entrants et sortants sur une seule année pourrait servir de répartition-type pour toutes les hypothèses retenues. Comme la structure des migrants fluctue en général d'une année à l'autre, il est courant de choisir une répartition-type moyenne portant sur une période de trois, cinq ou dix ans. On avait déjà adopté une technique semblable dans les projections précédentes en ce qui concerne la composition selon l'âge et le sexe des immigrants et des émigrants<sup>10</sup>; cette répartition est utilisée telle quelle tout au long de la période de projection.

En ce qui concerne les entrants et les sortants, on a eu recours à une méthode semblable. La répartition moyenne selon l'âge et le sexe des migrants pour la période de trois ans allant de 1968-69 à 1970-71 a été appliquée aux niveaux de migration prévus pour chaque province et territoire<sup>11</sup>.

**PARTIE II**  
PROJECTIONS DE LA POPULATION

## CHAPTER 6

### Projections Results

Combination of the various assumptions – one mortality, four fertility (including constant fertility assumption) and six migration (including zero migration) – arrived at in the preceding chapters would lead to numerous projections. Here, combinations of fertility and migration assumptions as shown in Appendix, were in the first phase chosen and programmed to produce population projections for Canada, provinces and territories through 2001. These projections results were in the second phase evaluated further in the light of past experiences and knowledge regarding the likely interrelationships between the two crucial variables of fertility and migration, and as a result, four sets called hereafter Projections A, B, C and D were selected to indicate the range of future population of Canada and provinces. The specific assumptions underlying these four projections are the following:

Projections C and D are almost similar for Canada. The slight difference between these two sets arises owing to the differentials in mortality and fertility among regions. However, the results of these

## CHAPITRE 6

### Résultats des projections

La combinaison des différentes hypothèses – une hypothèse pour la mortalité, quatre pour la fécondité (y compris l'hypothèse d'une fécondité constante), et six pour la migration (y compris l'hypothèse d'une absence de migration) – avancées dans les chapitres précédents donnerait lieu à un trop grand nombre de projections. Nous avons donc, dans une première phase, retenu douze combinaisons plausibles d'hypothèses de fécondité et de migration (voir l'appendice), à partir desquelles nous avons établi des projections de population pour le Canada, les provinces et les territoires jusqu'en l'an 2001. À la lumière de l'expérience et de la connaissance des relations probables entre les deux variables cruciales, la fécondité et la migration, les résultats de ces projections ont, dans une seconde phase, été évalués de façon plus approfondie; à la suite de quoi, nous avons sélectionné quatre combinaisons à savoir, les projections A, B, C et D. Les hypothèses spécifiques qui sont à la base de ces quatre projections sont les suivantes:

Les projections C et D sont pratiquement équivalentes au niveau du Canada. La légère différence qui existe entre les deux tient aux différences provinciales de mortalité et de fécondité. Par contre, au niveau des

Projection A: High fertility – Fécondité forte .....	2.60	100,000	450,000
Projection B: Medium fertility – Fécondité moyenne .....	2.20	60,000	435,000
Projection C: Low fertility – Fécondité faible .....	1.80	60,000	435,000
Projection D: Low fertility – Fécondité faible .....	1.80	60,000	218,000

<sup>1</sup> The mortality assumption is the same for all projections (see text). – L'hypothèse de mortalité est la même pour toutes les projections (voir texte).

two projections differ greatly for provinces illustrating the impact of alternative trends in interprovincial migration while fertility levels remain unchanged.

provinces, les résultats sont très éloignés l'un de l'autre, illustrant ainsi les conséquences de niveaux de migration interprovinciale différents, la fécondité étant la même dans les deux projections.

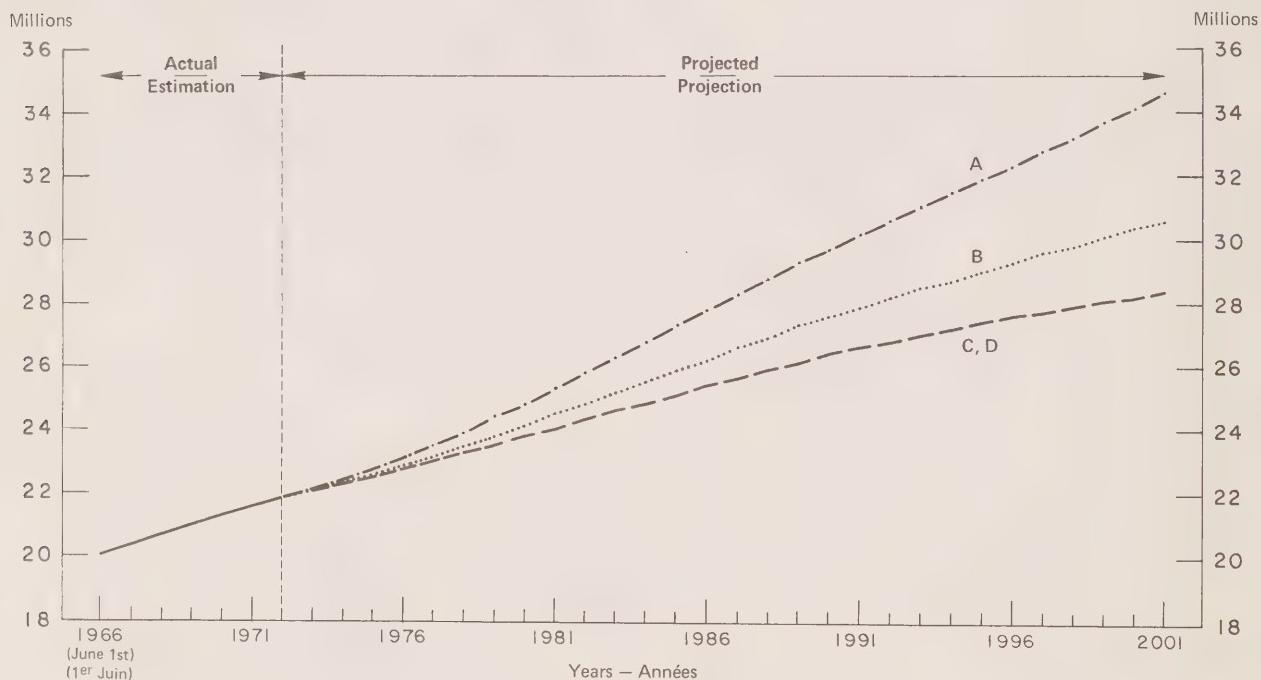

### Total Population

According to these four projections, the population of Canada which numbered 21.6 million in the 1971 Census, would lie between 25.4 and 27.8 million in 1986. To consider a longer period, Canada's population would reach between 28.4 and 34.6 million by 2001 as illustrated in Chart 6.1. The demographic outlook for provinces is shown in Table 6.2.

Chart – 6.1

### Projected Population of Canada to 2001 Projection de la population du Canada jusqu'en 2001

Graphique – 6.1

Ontario which had 7.7 million people in the last census, would exceed 10 million in 1986. However, in the event of either a decline in fertility below two children per woman assumed under Projection C, or a drop in migration in accord with Projection D, the population would fall below the 10 million mark. By the turn of this century, Ontario's population is expected between 11.2 and 14.7 million. The proportion of Ontario's population to Canada's population would go up from 35.7% in 1971 to about 38.4% (Projection C) or 39.3% (Projection A) in 1986.

The other two provinces that have usually gained population through migration, namely, British Columbia and Alberta, would also experience greater

L'Ontario, qui comptait 7.7 millions d'habitants au dernier recensement, dépasserait les 10 millions en 1986. Toutefois, dans le cas où la fécondité descendrait à moins de 2 enfants par femme (selon la projection C) ou s'il se produisait une chute de la migration (selon la projection D), cette population n'atteindrait pas 10 millions. La population ontarienne devrait, au début du prochain siècle, se situer entre 11.2 et 14.7 millions d'habitants. La proportion de la population ontarienne par rapport à celle du Canada devrait passer de 35.7 % en 1971 à 38.4 % (Projection C) ou 39.3 % (Projection A) en 1986.

Les deux autres provinces dont la population a généralement augmenté grâce à la migration, à savoir la Colombie-Britannique et l'Alberta, devraient également

additions to their populations in future. Thus, the population of British Columbia is anticipated around 3.2 million in 1986 or one million more people in fifteen years from 1971 to 1986. Roughly another million people would be added from 1986 to 2001, provided fertility and migration persist at levels assumed under Projection B. In terms of relative share, the proportion of British Columbia's population to the total population of Canada would continue to rise upward throughout this century from 10.1% in 1971 to 12.1% in 1986 and 13.9% in 2001. Alberta's population would exceed 2.1 million by 1986 and its share in the national population would climb from 7.6% to 8.1% during 1971-1986 according to Projection B. The long-term prospects indicate a population of 2.4 million under low migration Projection D and 3.0 million under Projection A.

The populations of the Yukon and Northwest Territories are projected around 28,000 and 58,000 respectively by 1986. By the turn of this century, the population in these two areas will approximate 39,000 and 92,000 according to Projection B.

Quebec, which in recent years experienced comparatively low fertility and migration loss, would have a population between 6.4 and 6.8 million in 1986 compared to 6.0 million in 1971. According to Projection B, the proportion of Quebec's population to the total population of Canada would drop from 28.0% in the last census to 25.2% by 1986. Quebec's relative share could be slightly higher around 25.9% if out-migration becomes less as under Projection D. In the event of positive migration to Quebec, the population is anticipated to be about 7.1 million in 1986 or 26.4% of the national population (see Chapter 7 and Part III).

Projections results for other provinces, shown in Table 6.2, indicate that Manitoba would have between 1,006,000 and 1,119,000 population by 1986. The Atlantic provinces could expect but a small expansion in their populations in the coming years. The ranges in population size projected for these provinces are: Newfoundland 610,000 to 661,000, Prince Edward Island 119,000 to 128,000, Nova Scotia 817,000 to 890,000 and New Brunswick 675,000 to 720,000 in 1986.

As far as Saskatchewan is concerned, the projections examined here reveal a decrease in the total population of this province. If this province continues to experience losses through migration at rates assumed in these projections, the size of its population may diminish from 926,000 in 1971 to range between 758,000 and 905,000 in 1986. However, in the event that migration less ceases in the years to come, this province's population is expected to increase due to

connaître un accroissement démographique considérable dans l'avenir. On prévoit que la population de la Colombie-Britannique s'élèvera aux environs de 3.2 millions en 1986, soit un million d'habitants de plus en 15 ans (1971-1986). On considère qu'un autre million devrait s'ajouter entre 1986 et 2001, si la fécondité et la migration se maintiennent aux niveaux prévus par la projection B. En proportion du total canadien, la population de la Colombie-Britannique devrait continuer à grimper jusqu'à la fin du siècle et passer de 10.1 % en 1971 à 12.1 % en 1986 et à 13.9 % en 2001. La population de l'Alberta devrait dépasser 2.1 millions d'habitants en 1986 et sa proportion devrait passer de 7.6 % à 8.1 % entre 1971 et 1986 toujours selon la projection B. Les projections à long terme laissent entrevoir une population de 2.4 millions d'habitants (projection D, migration faible) ou 3.0 millions (projection A).

Les populations du Yukon et des Territoires du Nord-Ouest devraient atteindre 28,000 et 58,000 habitants respectivement en 1986. Au début du prochain siècle, la population de ces territoires devrait approcher les 39,000 et 92,000 selon la projection B.

Le Québec qui a, ces dernières années, connu une fécondité comparativement faible et une migration nette négative, devrait compter de 6.4 à 6.8 millions d'habitants en 1986 comparativement à 6.0 millions en 1971. Selon la projection B, la proportion de la population du Québec dans l'ensemble du Canada devrait tomber de 28.0 % (au dernier recensement) à 25.2 % en 1986. Cette proportion pourrait être légèrement supérieure et atteindre 25.9 % si moins de gens quittaient la province (projection D). Dans le cas où le solde migratoire au Québec deviendrait positif, la population devrait atteindre environ 7.1 millions en 1986, soit 26.4 % de la population du Canada (voir chapitre 7 et partie III).

Les résultats des projections concernant les autres provinces, présentés au tableau 6.2, montrent que la population du Manitoba se situerait entre 1,006,000 et 1,119,000 habitants en 1986. Quant aux provinces de l'Atlantique elles ne connaîtraient qu'un faible accroissement de leurs populations dans les années à venir. Les projections montrent que l'échelle des populations de ces provinces, en 1986, s'établirait comme suit: Terre-Neuve 610,000 à 661,000 habitants; Île-du-Prince-Édouard 119,000 à 128,000; Nouvelle-Écosse 817,000 à 890,000 et Nouveau-Brunswick 675,000 à 720,000.

Quant à la Saskatchewan, les projections présentées ici prévoient un déclin de la population. Si cette province continue à connaître un solde migratoire négatif au rythme prévu par nos projections, sa population risque de tomber de 926,000 habitants, en 1971, aux environs de 758,000 à 905,000 en 1986. Toutefois, dans le cas où on assisterait à un équilibre dans les échanges migratoires au cours des prochaines années, la population de cette province devrait alors augmenter

the excess of births over deaths. According to Projection E, discussed in Chapter 7, that assumes zero migration, the population of Saskatchewan could reach a figure of 1,100,000 by 1986.

### Indicated Growth

The population of Canada numbered 21,568,000 in the 1971 Census. This was an increase of 7.8% (or 1,553,000) during the intercensal period 1966-1971 as compared to 9.7% in the earlier intercensal period 1961-1966. This **deceleration** in the growth of Canada's population is anticipated to continue under all four projections during 1971-1976. Furthermore, the population increase would be less in absolute number as well. Thus, the high Projection A shown in Table 6.2 indicates a growth of 1,518,000 in this period or 35,000 fewer than the increase of 1,553,000 during 1966-1971. Under low Projection D, the growth would approximate 1,202,000 which is far short by 351,000 compared to the increase in the previous intercensal period. The growth according to Projection B would be 1,278,000 which would be about 275,000 or 18% lower than the growth during 1966-1971.

Projections for the period after 1976, however, indicate a general **rise** in absolute growth under all four series. The increase would differ largely from one series to another. Both Projections A and B show an absolute increase exceeding 1,553,000 recorded during 1966-1971; in relative terms, however, the growth would be less at 7.1% under Projection B compared to 7.8% from 1966 to 1971; but, far greater under Projection A at 9.6% from 1976 to 1981 and 9.9% from 1981 to 1986. Compared to 1966-1971 period, the absolute and relative growth under Projections C and D are less and tend to stabilize around 5.6% per quinquennium.

The population growth beyond 1986 to 2001, which is subject to greater errors, is also presented in Chart 6.2 which illustrates a cyclical pattern of population growth in Canada over the next thirty years. This pattern of growth which is due to the post-war baby boom, is more or less expected to take place across the country; however, underneath this similarity of pattern, would lie substantial differentials in rates of increase of population among the provinces as indicated by Table 6.3.

### Period 1971-1976

With respect to growth, this period, as noticed earlier for Canada, would be characterized by a **downward** trend in most provinces according to Projections B and C and the population growth would frequently be less in number than that that took place

grâce à l'excédent des naissances sur les décès. Selon la projection E, présentée au chapitre 7, et qui suppose un solde migratoire nul, la population de la Saskatchewan pourrait atteindre le chiffre de 1,100,000 en 1986.

### Croissance prévue

La population canadienne était, d'après le recensement de 1971, de 21,568,000 habitants. Ceci représentait une augmentation de 7.8 % (soit 1,553,000 habitants) au cours de la période intercensitaire 1966-1971 comparativement à 9.7 % lors de la précédente période 1961-1966. Selon les quatre projections, cette **diminution** du rythme de croissance de la population canadienne devrait se poursuivre au cours de la période 1971-1976. En outre, l'augmentation de la population sera moindre en valeur absolue. Ainsi, la projection A (hypothèses fortes) prévoit un accroissement de population de 1,518,000 habitants au cours de cette période, soit 35,000 de moins que durant la période 1966-1971 (1,553,000) comme on le voit au tableau 6.2. Selon la projection faible (D) la croissance sera approximativement de 1,202,000, soit 351,000 de moins que durant la précédente période. Selon la projection B, la croissance serait de 1,278,000 habitants, soit 18 % de moins (ou 275,000) qu'entre 1966 et 1971.

Toutefois, pour la période postérieure à 1976, les quatre projections indiquent une **augmentation** générale, en valeur absolue, de l'accroissement de population. Cet accroissement varie considérablement d'une projection à l'autre. Les projections A et B prévoient toutes deux un accroissement supérieur à celui de 1,553,000 enregistré en 1966-1971; proportionnellement, toutefois, la croissance serait moindre selon la projection B, soit 7.1 % comparativement à 7.8 % entre 1966 et 1971; mais elle serait de beaucoup supérieure selon la projection A, soit 9.6 % de 1976 à 1981 et 9.9 % de 1981 à 1986. D'après les projections C et D et comparativement à la période 1966-1971, la croissance tant absolue que relative serait moindre et tendrait à se stabiliser autour de 5.6 % par période de 5 ans.

La croissance démographique de 1986 à 2001, sujette à une plus forte marge d'erreur, est également présentée dans le graphique 6.2 qui illustre le caractère cyclique de la croissance de la population au Canada au cours des 30 prochaines années. On s'attend à ce que cette évolution inégale, due à l'explosion démographique de l'après-guerre, soit plus ou moins générale à travers le pays; cependant, parallèlement à cette similitude d'évolution, on pourra observer des différences considérables dans les taux d'accroissement de population des diverses provinces, comme le montre le tableau 6.3.

### Période 1971-1976

Durant cette période, comme on l'a déjà dit pour le Canada, la croissance de la population se caractériserait par une tendance à la **baisse** dans la plupart des provinces, si l'on s'en tient aux projections B et C, et serait généralement inférieure, en nombre absolu, à celle que le

Chart - 6.2

**Components of Growth, Canada, 1956-71 Observed, 1972-2001 Projection B**  
**Composantes de la croissance de la population canadienne,**  
**1956-71, estimations, 1972-2001 selon la projection B**

Graphique - 6.2

during 1966-1971. To consider the above-average growth provinces in Table 6.3, the population increase in Ontario would range from 640,000 to 667,000 or 8.3% to 8.7% under Projections B and C as compared to a rise of 742,000 or 10.7% in 1966-1971. Under Projection A, however, the growth would be slightly higher at 828,000 whereas the national increase would be downward during 1971-1976 even under this high series. A similar pattern of numerical increase over 1971-1976 would be witnessed in British Columbia, Alberta and the Northwest Territories (see Table 6.3).

All other provinces, excepting Newfoundland and New Brunswick, would experience, according to Projections B, lower growth in numbers during 1971-1976 than that which took place during 1966-1971. Some of these provinces would, however, experience higher absolute growth than during 1966-1971 if migration slows down as under Projection D (New Brunswick, Manitoba, Newfoundland and Prince Edward Island) or if fertility increases according to Projection A (New Brunswick and Newfoundland). Quebec is projected to have lower growth during this period under all series ranging from 113,000 to 158,000 or 1.9% to 2.6% compared to a growth of 247,000 or 4.3% in 1966-1971.

pays a connue entre 1966 et 1971. D'après le tableau 6.3 certaines provinces jouissent d'une croissance supérieure à la moyenne. C'est ainsi que l'accroissement de la population de l'Ontario pourrait se situer entre 640,000 et 667,000 habitants (soit 8.3 % et 8.7 %) selon les projections B et C comparativement à l'accroissement de 742,000 soit 10.7 % observé entre 1966 et 1971. Toutefois, selon la projection A cette croissance serait plus importante (828,000 environ); mais la tendance du pays dans son ensemble serait néanmoins à la baisse entre 1971 et 1976. On devrait observer le même type de croissance en Colombie-Britannique, en Alberta et dans les Territoires du Nord-Ouest entre 1971 et 1976 (voir tableau 6.3).

Quant aux autres provinces (à l'exception de Terre-Neuve et du Nouveau-Brunswick) leur croissance, selon la projection B, serait moindre que celle de la période 1966-1971. Certaines provinces devraient cependant connaître une croissance supérieure, en valeur absolue, à celle observée pendant la période précédente (1966 à 1971), si les migrations diminuent comme on le suppose dans la projection D (Nouveau-Brunswick, Manitoba, Terre-Neuve et Île-du-Prince-Édouard) ou encore si la fécondité augmente comme le prévoit la projection A (Nouveau-Brunswick et Terre-Neuve). Toutes les projections prévoient pour le Québec une croissance inférieure pour cette période, soit 113,000 à 158,000 habitants (1.9 % et 2.6 %) comparativement à un accroissement de 247,000 habitants (4.3 %) observé entre 1966 et 1971.

### Period 1976-1986

This period is expected to mark a general **upward** trend in population growth across the nation. All provinces, excepting Saskatchewan, would witness according to Projection B larger growth in absolute and percentage terms than that projected for 1971-1976, and some provinces, notably Ontario, British Columbia and Alberta would experience absolute growth in excess of that recorded during 1966-1971. Thus, Projection B indicates an increase of 818,000 (i.e., 9.8%) in Ontario, 340,000 (i.e. 13.7% in British Columbia and 173,000 (i.e. 9.8%) in Alberta during 1976-1981. This upward demographic trend could be attributed to the baby boom generation that would be passing through reproductive ages in this period.

However, it should be pointed out here that the demographic buoyancy in Projection B, anticipated during this period, may not happen should women of post-war years have changed attitudes towards family size and opt for less than two children per family as implied in Projection C. In this situation, the downward trend in growth rates anticipated during 1971-1976 would continue through the 1970's and 1980's as indicated by Projection C.

This effect of the baby boom generation would continue into 1981-1986 and consequently, the foregoing trends corresponding to Projection B and Projection C would persist among the provinces. In the event of falling fertility the differential rate of growth of population in provinces would greatly depend, more than ever before, on the role of migration as illustrated in Chart 6.3.

### Period 1986-2001

Projections for this period indicate a general **downward** trend for all provinces as the cohorts of the baby boom would complete their reproductive ages and the momentum of potential upward trend during 1976-1986 comes to a stop. Attitudes of the post baby boom cohorts, smaller in numbers, towards family size are difficult to foresee; nevertheless, the inclination seems towards lower fertility and consequently, this period could witness a reduction in provincial differences in rates of population growth and an emergence of a universal low rate of natural increase across the country.

### Changes in Age Composition

The dimensions of population size and growth are one face of the demographic processes. Interlinked closely to this process is the changing age-sex structure of population which is in nature cumulative year by year as the new cohorts of babies age to become the school children, the working adults, the family mem-

### Période 1976-1986

Au cours de cette période on s'attend généralement à une augmentation du rythme de croissance de la population dans tout le Canada. La projection B prévoit, dans toutes les provinces à l'exception de la Saskatchewan, une croissance supérieure (en valeur absolue et en pourcentage) à celle de la période précédente. La croissance en valeur absolue de la population dans certaines provinces, en particulier l'Ontario, la Colombie-Britannique et l'Alberta, devrait même dépasser celle observée de 1966 à 1971. Ainsi, la projection B indique une augmentation de population de 818,000 habitants en Ontario (+ 9.8 %), 340,000 en Colombie-Britannique (+ 13.7 %) et 173,000 en Alberta (+ 9.8 %) pour la période 1976-1981. Cette hausse pourrait être attribuée aux effectifs très nombreux des générations d'après-guerre qui seraient alors en âge de procréer.

Toutefois, il convient de noter que la poussée démographique prévue pour cette période par la projection B pourrait ne pas de produire si, comme le suppose la projection C, les femmes nées après la guerre ne conçoivent plus la famille de la même façon et décident d'avoir moins de deux enfants par famille. Dans ce cas, la tendance à la baisse prévue pour 1971-1976 se poursuivrait dans les années 70 et 80 comme l'indique la projection C.

Les répercussions de l'explosion démographique d'après-guerre devraient se faire encore sentir entre 1981 et 1986 et, par conséquent, les tendances précédentes correspondant aux projections B et C devraient persister dans toutes les provinces. En cas de baisse de la fécondité, les différences de taux de croissance d'une province à l'autre dépendraient, plus que jamais, du niveau des migrations (voir graphique 6.3).

### Période 1986-2001

On prévoit pour cette période une tendance générale à la baisse pour toutes les provinces, les générations d'après-guerre ayant alors achevé leur période de procréation et la poussée démographique qu'elles auraient provoquée entre 1976 et 1986 arriverait alors à son terme. Il est difficile de prévoir les attitudes des générations récentes envers la procréation; néanmoins un faible niveau de fécondité semble probable et, par conséquent, on pourrait assister à une réduction des écarts entre provinces dans les taux de croissance de la population. Un faible taux d'accroissement naturel pourrait alors se généraliser dans tout le pays.

### Évolution de la structure par âge

La taille et la croissance de la population ne représentent qu'un aspect des résultats du processus démographique. Un autre aspect important concerne les modifications de la structure par âge et sexe de la population. Cette structure est essentiellement le résultat d'un cumul, année par année, de nouvelles générations

bers and the retired/aged. It is already noticed (p. 68) how closely the upward trend in population growth during 1976-1986 would depend on the changing structure of population.

The important demographic development in the 'fifties and 'sixties had been the baby boom followed by a sharp decline in fertility after 1959. The effects of these cohorts on population structure deserve close attention here. Besides, the current low fertility and its future course on the one hand and annual migration on the other would exert great influences on the over-all population structure and on trends in major segments of population. The expected changes in population structure under alternative Projections B and C are depicted in Chart 6.4.

#### Population 0 to 14 Years

It is important to note that the young population 0 to 14 would hardly grow by 1% during 1971-1986 according to Projection B. Under low fertility assumption (i.e. Projection C), this group which numbered 6.3 million in 1971 could drop to 5.6 million or by 12.7% as indicated in Chart 6.5. In the short term 1971-1976, this group would decline between 8% to 9% under both Projections B and C. Projected changes

qui, successivement, parviennent à l'âge scolaire puis entrent sur le marché du travail, atteignent l'âge de fonder une famille puis l'âge de la retraite. On a déjà noté (p. 68) l'étroite liaison qui existe entre l'accroissement prévu de population de 1976 à 1986 et la structure de départ de la population selon l'âge et le sexe.

L'évolution démographique des années 50 et 60 a été caractérisée par l'explosion démographique d'après-guerre suivie d'un net déclin de la fécondité depuis 1959. L'influence de ces générations sur la structure de la population mérite qu'on s'y arrête. En outre, la faible fécondité actuelle et ses perspectives d'évolution d'une part et les migrations annuelles d'autre part pourraient exercer une influence considérable sur la structure tant de l'ensemble de la population que de sa répartition par grands groupes d'âges. On trouvera au graphique 6.4 les modifications anticipées dans la structure de la population, selon les projections B ou C.

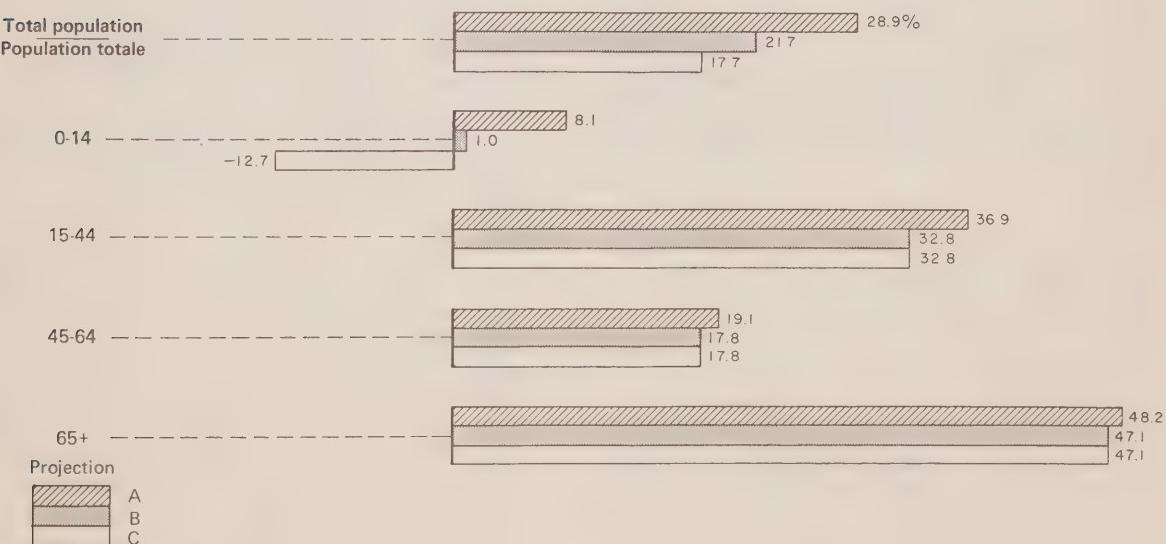

#### Population de 0 à 14 ans

Il est important de noter que selon la projection B, la population de 0 à 14 ans augmenterait à peine de 1 % au cours de la période 1971-1986. Dans l'hypothèse d'une faible fécondité (voir projection C), ce groupe qui comptait, en 1971, 6.3 millions de personnes pourrait descendre à 5.6 millions (soit une baisse de 12.7 %) comme on peut le voir au graphique 6.5. À court terme (1971-1976), il pourrait, selon les projections B et C,

Source: See part III. — Source : Troisième partie de ce rapport.

for provinces indicate a decrease across the nation excepting the Yukon and Northwest Territories ranging from 5% to 20% during 1971-1976. In the period 1971-1986, the medium fertility Projection B shows an increase in Ontario, Alberta and British Columbia and a decrease in the remaining provinces. On the other hand, if women begin to have fewer than two children as under Projection C, this group will decline during 1971-1986 between 2% (Ontario) to 40% (Saskatchewan) in all provinces excepting only British Columbia.

In this group, the population at age 6 when children enter the school system is of interest to the users and therefore, projected trends for this key age illustrated in Chart 6.6 indicate that the size will not, in the next fifteen years, reach again the previous peak of 482,000 in 1967-68 under Projections B or C. Should fertility recover to a high level, this cohort will then grow in excess of 482,000 in 1984. In the short term 1971-1976, this cohort will fluctuate between 364,000 and 387,000 because of the smaller number of births since 1967.

#### Population 15 to 44 Years

This group represents perhaps the most important segment of the population for many reasons. Economically, it determines the growth and structure of the labour force. Demographically, it determines the number of births, the rate of family and household formation and of migration across the country. During 1971-1986, this group consisting of the entire baby boom generation is expected to grow faster than the total population recording an over-all increase between 33% to 37% (see Chart 6.5). There will be about 12.5 to 12.9 million persons 15 to 44 years in 1986 as compared with 9.4 million in 1971 or an average increase of 200,000 to 235,000 persons annually. The growth during successive five-year periods is projected to differ considerably and according to Projection B it will average about 243,000 a year during 1971-1976, 234,000 during 1976-1981 and 140,000 during 1981-1986.

Projected changes in this group for provinces indicate a far wider variation from the rates of growth in their total populations during 1971-1986. The specific growth will vary from 15% in Manitoba to 63% in British Columbia according to Projection B. For Ontario and Alberta, the corresponding growth rate will amount to 42% reflecting (for British Columbia as well) the combined influences of the post-war high fertility and of the consistent gain through migration whereas in the same vein, it is to be pointed out that the out-migration provinces indicate percentage increases lower than the national average of 33% for this age group. Under Projection D, involving low mi-

diminuer de 8 à 9 %. Au niveau des provinces à l'exception du Yukon et des Territoires du Nord-Ouest, on pourrait assister à une diminution générale de l'ordre de 5 % à 20 % au cours de la période 1971-1976. Durant la période 1971-1986, selon la projection B (fécondité moyenne), il y aurait augmentation en Ontario, en Alberta et en Colombie-Britannique et diminution dans les autres provinces. D'autre part, si les femmes décidaient d'avoir moins de deux enfants, tel que supposé dans la projection C, ce groupe diminuerait, au cours de 1971-1986, de 2 % (Ontario) à 40 % (Saskatchewan) dans toutes les provinces à l'exception de la Colombie-Britannique.

À l'intérieur de ce groupe, la population des enfants de 6 ans (c'est-à-dire le début de la scolarité) intéresse particulièrement les utilisateurs. Selon les projections B et C il semble que dans les 15 prochaines années, ce groupe n'atteindra pas le sommet de 482,000 atteint en 1967-68 (voir graphique 6.6). Si la fécondité retrouvait un niveau élevé, ce groupe dépasserait alors les 482,000 en 1984. À court terme (1971-1976), ce groupe oscillera entre 364,000 et 387,000 compte tenu du nombre plus faible de naissances depuis 1967.

#### Population de 15 à 44 ans

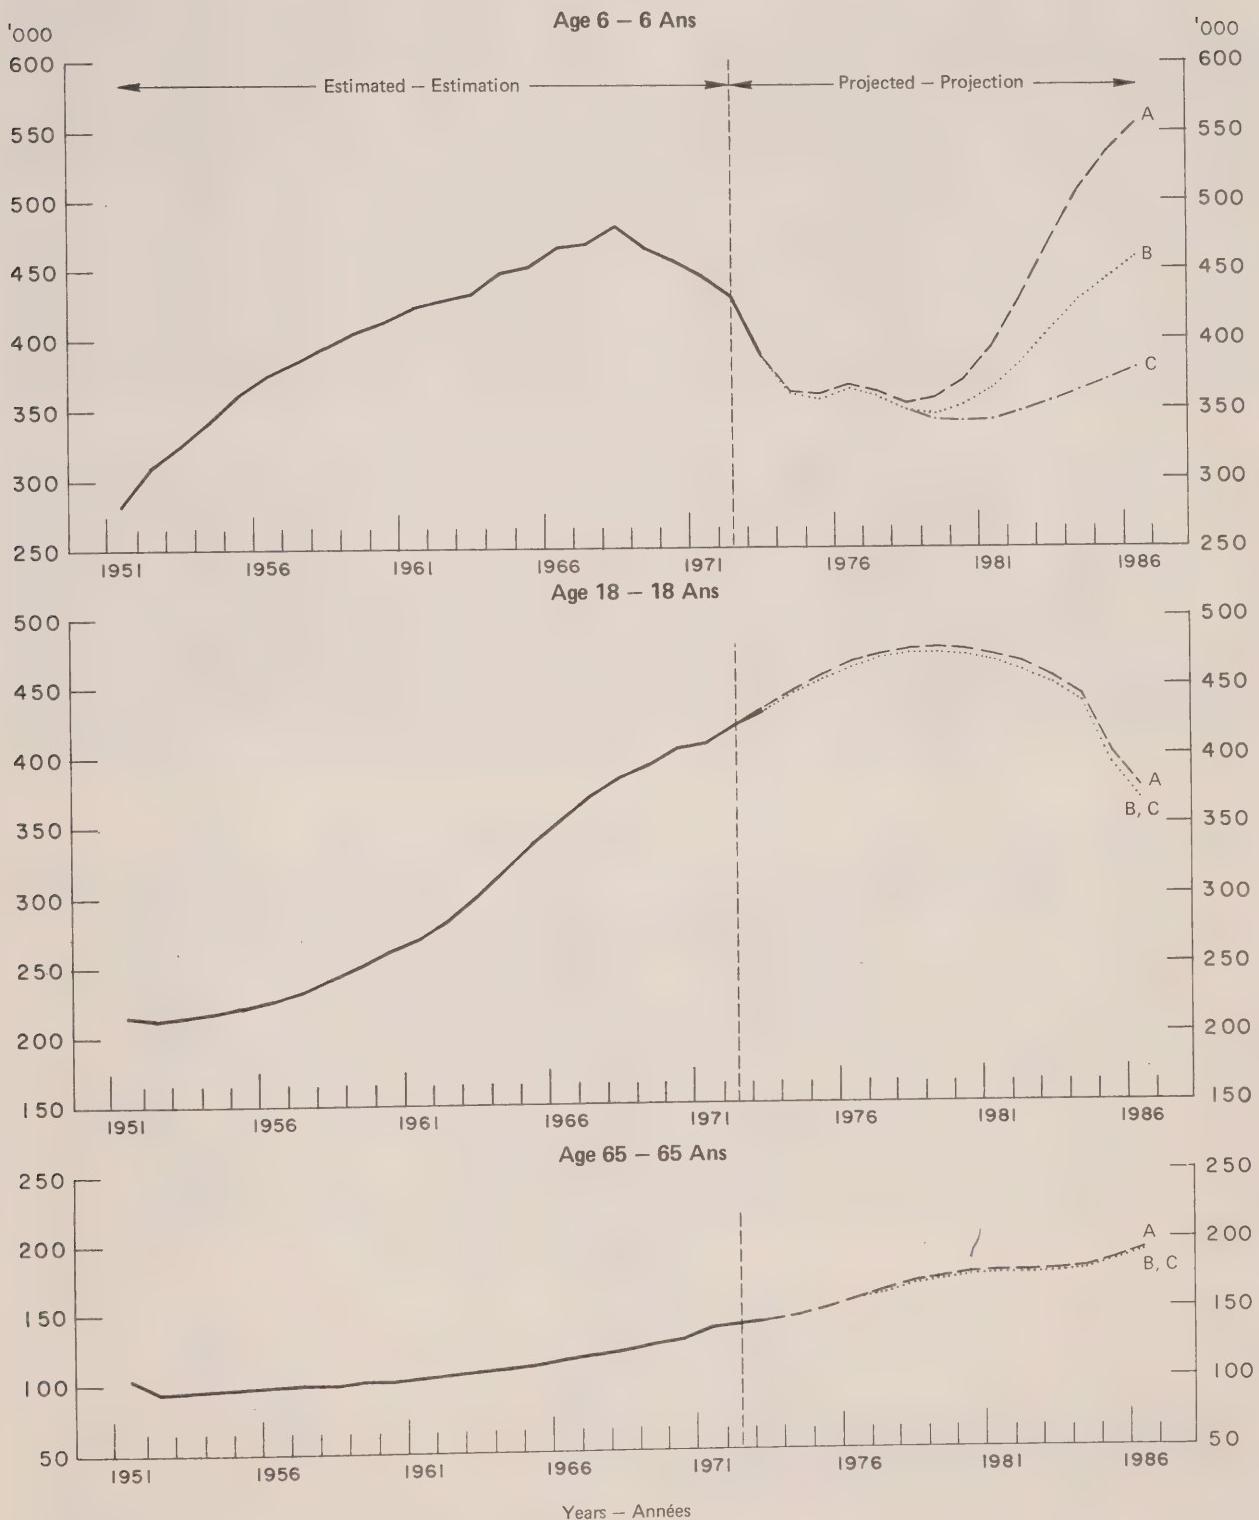

Ce groupe représente peut-être le segment le plus important de la population et ce pour plusieurs raisons. Au point de vue économique c'est lui qui détermine la croissance et la structure de la population active. Au point de vue démographique, il détermine le nombre des naissances, le taux de formation des ménages et des familles et le taux de migration à travers le pays. Entre 1971 et 1986, ce groupe, constitué des générations d'après-guerre, pourra croître plus rapidement que la population totale, son augmentation variant entre 33 % et 37 % (voir graphique 6.5). Il y aura de 12.5 à 12.9 millions de personnes de 15 à 44 ans en 1986 comparativement à 9.4 millions en 1971, soit une augmentation moyenne de 200,000 à 235,000 personnes par an. La croissance variera considérablement selon la période quinquennale considérée; selon la projection B, on pourrait voir une augmentation moyenne de 243,000 personnes par an entre 1971 et 1976, de 234,000 entre 1976 et 1981 et de 140,000 entre 1981 et 1986.

Au niveau des provinces, le taux de croissance de ce groupe d'âges pourrait différer largement du taux de croissance prévu pour leur population totale au cours de la période 1971-1986. Selon la projection B, l'accroissement respectif pourrait varier entre 15 % (Manitoba) et 63 % (Colombie-Britannique). Pour l'Ontario et l'Alberta, les taux de croissance correspondants s'élèveraient à 42 %, reflétant, comme pour la Colombie-Britannique, l'influence combinée de la forte fécondité d'après-guerre et des gains migratoires importants. Il faut également remarquer que les provinces "perdantes" au point de vue migration connaîtront une croissance relative plus faible que la moyenne nationale (33 %). Par ailleurs ces écarts seraient

Source: Unpublished data — Source : Données non publiées

gration, these wide variations are expected to be less among the provinces.

#### Population 45 to 64 Years

The number of persons 45 to 64 years is anticipated to increase from 4.0 million in 1971 to 4.7 million in 1986 under Projection B. This will denote an over-all increase of 18% which is below the expected growth of the total population. One explanation is that the group is composed of births during the 'twenties and 'thirties when the total fertility was on its downward course culminating by 1937 in the lowest rate for the pre-war period. Growth in this group will however be substantial after 1986 as the baby boom generation will reach this age group, and the size according to Projection B will approximate 6.7 million in 2001 indicating an expansion of 2 million during 1986-2001 in contrast to about three fourths of a million in 1971-1986.

Future trends in this group are expected to vary strikingly among the provinces. According to Projection B, the number of persons 45 to 64 will diminish between 3% to 8% in Prince Edward Island, Nova Scotia, New Brunswick and Manitoba during 1971-1986. The decrease will amount to 23% in Saskatchewan in the same period. In contrast, Newfoundland and Quebec will have lower growth than the national increase of 17.8% while Ontario, Alberta and British Columbia will experience above-average increases between 25% to 33% in this period.

#### Population 65 Years and Over

There were 1.7 million people aged 65 years and over in 1971 and Projection B indicates a size of 2.6 million by 1986 or an increase of 47% which, as evidenced by Chart 6.5, will be the fastest growing segment of the population in the coming years. Besides the steady decline of mortality over the past, the relatively high fertility and the large immigration in the beginning of this century will explain this expected large increase in the elderly population. After 1986, however, the increase will be less in the light of the aforesaid below-average growth in the age group 45 to 64 during the period 1971-1986, and the expected population of this group is about 3.3 million in 2001.

The prospects for this age group are divergent among the provinces as illustrated in Chart 6.7. No province is expected to experience a reduction in the number of persons 65 years and over. The lowest growth will be 15% during 1971-1986 in Prince Edward Island and the highest (excluding Yukon and the Northwest Territories) about 56% in Alberta reflecting the influence, among other factors, of the longest expectation of life in this province.

moins marqués selon la projection D qui suppose une migration faible.

#### Population de 45 à 64 ans

La projection B prévoit que le nombre de personnes âgées de 45 à 64 ans passera de 4.0 millions en 1971 à 4.7 millions en 1986. Cela signifie une augmentation globale de 18%, chiffre qui se situe nettement au-dessous du taux de croissance prévu pour l'ensemble de la population. On peut expliquer cela par le fait que ce groupe est composé de personnes nées dans les années 20 et 30, période d'avant-guerre ayant connu une fécondité très faible, avec son taux le plus bas en 1937. Toutefois, la croissance de ce groupe s'accélérera après 1986, lorsque les générations d'après-guerre en feront partie: sa taille, selon la projection B, serait alors d'environ 6.7 millions en 2001, soit un accroissement de 2 millions entre 1986 et 2001, comparativement au trois-quart de million prévu entre 1971 et 1986.

L'évolution de ce groupe dans les années à venir devrait être très différente d'une province à l'autre. Selon la projection B, le nombre de personnes de 45 à 64 ans diminuera de 3 à 8% dans l'Île-du-Prince-Édouard, en Nouvelle-Écosse, au Nouveau-Brunswick et au Manitoba entre 1971 et 1986. Au cours de la même période, cette baisse atteindra 23% en Saskatchewan. Par contre, le Québec et Terre-Neuve connaîtront un taux de croissance plus faible que le taux national (17.8%) alors que la croissance en Ontario, en Alberta et en Colombie-Britannique se situera au-dessus de la moyenne, soit de 25% à 33%.

#### Population de 65 ans et plus

En 1971, le nombre des personnes âgées de 65 ans et plus s'élevait à 1.7 million; la projection B en prévoit 2.6 millions en 1986, soit une augmentation de 47% (voir graphique 6.5). Ce groupe sera donc celui qui connaîtra la croissance la plus rapide dans les années à venir. Cet important accroissement de la population âgée s'explique par la baisse continue de la mortalité d'une part et par la fécondité relativement élevée et la forte immigration qui ont caractérisé le début de ce siècle d'autre part. Après 1986, toutefois, cet accroissement sera moindre étant donné la faible croissance des 45 à 64 ans, au cours de la période 1971-1986, expliquée précédemment. La population de 65 ans et plus devrait s'élever à 3.3 millions de personnes environ en 2001.

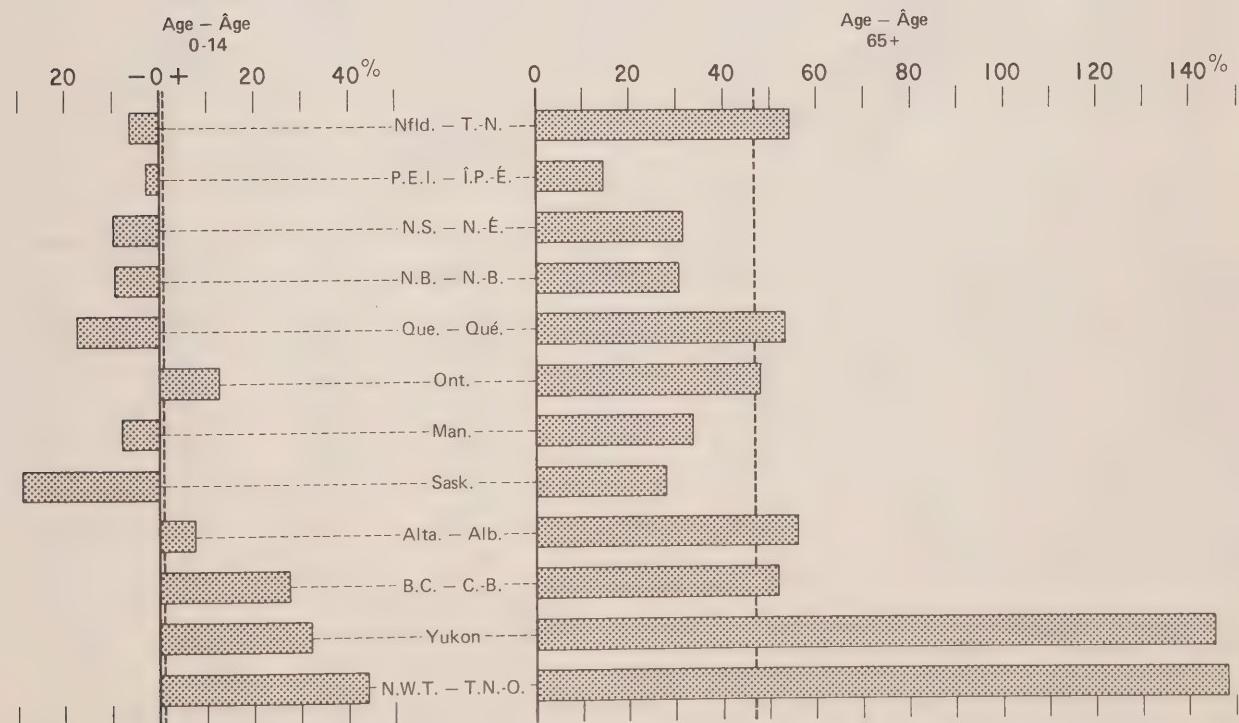

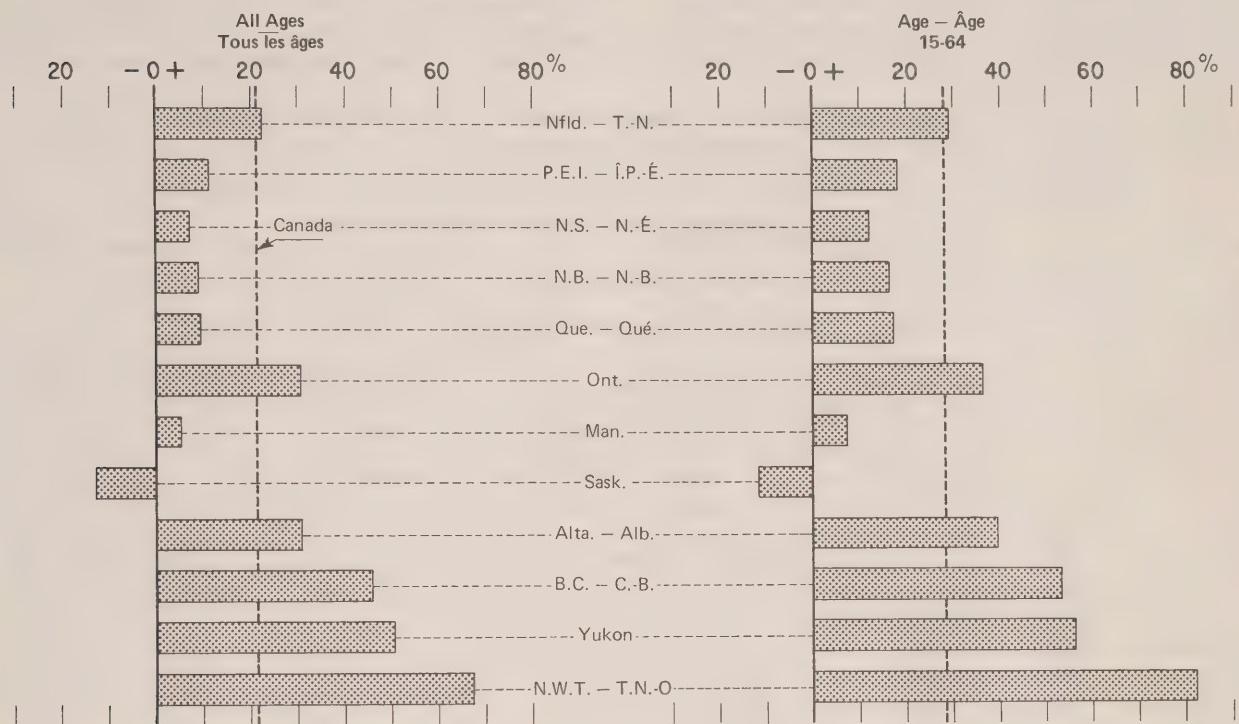

Les perspectives concernant ce groupe d'âges diffèrent d'une province à l'autre comme le montre le graphique 6.7; cependant, aucune province ne devrait connaître de réduction du nombre des personnes de 65 ans et plus. C'est l'Île-du-Prince-Édouard qui aura la plus faible croissance (15%) entre 1971 et 1986 tandis que la plus forte (si on fait exception du Yukon et des Territoires du Nord-Ouest), sera observée en Alberta (56%) ce qui reflète, entre autres facteurs, l'influence de l'espérance de vie plus longue dans cette province.

Source: See part III. — Source : Troisième partie de ce rapport.

The over-all effects of shifts in population structure resulting from the foregoing differential trends in specific age groups are indicated in Table 6.4. Under Projection B, the proportion of population 0-14 years will diminish from 29.6% in 1971 to 24.5% in 1986 and 22.7% in 2001. It could drop as low as 19.6% by the end of this century as indicated by Projections C and D. The working ages group 15 to 64 will increase

Le tableau 6.4 présente les répercussions sur la structure de la population de l'évolution différentielle des divers groupes d'âges. Selon la projection B, la part des 0 à 14 ans dans la population totale passera de 29.6 % en 1971 à 24.5 % en 1986 et à 22.7 % en 2001. Elle pourrait même descendre à 19.6 % à la fin du siècle, selon les projections C et D. Le groupe des actifs (15 à 64 ans) passera de 62.3 % selon le dernier recensement à 65.7 %

Sources: J. Yam "Selected Parameters Relevant to the Age-Sex Structure of Canada's Population", *Population and Housing Research Memorandum No. PH - DC-4* (Ottawa: Statistics Canada, March 1973) p. 5; and Part III. — J. Yam "Selected Parameters Relevant to the Age-Sex Structure of Canada's Population", *Population and Housing Research Memorandum no PH - DC-4* (Ottawa: Statistique Canada, mars 1973) p. 5; et troisième partie de ce rapport.

from 62.3% at the last census to 65.7% in 1986 according to medium fertility. Similarly, the proportion of persons 65 years and over will go up to 10% in 1986 from that of 8% in 1971.

In terms of a summary index, the dependency ratio will drop during 1971-1986. These ratios calculated in Table 6.4 indicate also a downward trend for all provinces. Quebec shows the lowest ratio, about 47 dependants per 100 persons 15 to 64 years and Saskatchewan the highest ratio of 66 dependants in 1986 according to Projection B.

### Sex Composition

In the 1971 Census, the males exceeded the number of females by 22,000. Projected trends imply a sex ratio in favour of females, and the number of females in the population could exceed by 175,000 in 1986 under Projection B. This will correspond to a sex ratio of 987 males per 1,000 females. The ratios for provinces suggest a general trend in favour of females due possibly to the cumulative effects of higher expectation of life among women than men, and the more balanced distribution of sexes among migrants in recent years. Notwithstanding, Newfoundland, Alberta, British Columbia, the Yukon and Northwest Territories are projected to have more males than females in 1986. In all other provinces, the sex ratio will range from 963 to 994 males per 1,000 females as shown in Table 6.4.

en 1986 dans le cas d'une fécondité moyenne et la proportion des personnes de 65 ans et plus, de 8 % en 1971 à 10 % en 1986.

Entre 1971 et 1986, la proportion de personnes à charge va diminuer au Canada et dans chacune des provinces (tableau 6.4). Selon la projection B, le Québec présentera la proportion la plus faible avec environ 47 personnes à charge pour cent personnes de 15 à 64 ans, tandis que la Saskatchewan enregistrera la plus forte avec 66 personnes à charge en 1986.

### Répartition selon le sexe

Le recensement de 1971 a montré qu'il y a au Canada plus d'hommes que de femmes, le surplus étant de l'ordre de 22,000. Dans l'avenir cependant le rapport de masculinité devrait favoriser le sexe féminin et, selon la projection B, le nombre de femmes pourrait représenter un excédent de 175,000 en 1986, ce qui correspond à un rapport de masculinité de 987 hommes pour 1,000 femmes. Au niveau provincial les rapports favorisent également le sexe féminin. Cela peut provenir de l'effet cumulatif d'une espérance de vie plus longue chez les femmes ainsi que d'une répartition des sexes plus équilibrée parmi les migrants dans les dernières années. Par contre, on prévoit que Terre-Neuve, l'Alberta, la Colombie-Britannique et les Territoires du Nord-Ouest compteront encore plus d'hommes que de femmes en 1986. Dans toutes les autres provinces, le rapport sera de l'ordre de 963 à 994 hommes pour 1,000 femmes, comme le montre le tableau 6.4.

## CHAPTER 7

### Other Projections Series

As stated in the preceding chapter, several sets of projections were made by Statistics Canada and Projections A, B, C and D were selected out of them to depict the demographic outlook for Canada and provinces. Besides these four projections, the following three sets are considered valuable for publication. The first series, called Projection E, is based on zero migration both at international and interprovincial levels with constant fertility through 2001. These hypothetical projections are needed by demographers for many theoretical studies and are found also useful in many policy studies.

The second set, namely Projection F, is intended here to meet the U N standard regarding projections and assumes, as in Projection E, that the future fertility will be constant at the level observed during the base period of projections. Mortality and migration assumptions are, however, the same as in Projection A (see Table 6.1). The specific fertility level used for each province is given in Table 7.1.

**TABLE 7.1. Fertility and Migration Assumptions<sup>1</sup> Underlying Projections E, F and G,  
Canada and Provinces, 1972 - 2001**

## CHAPITRE 7

### Projections additionnelles

Comme nous l'avons dit dans le chapitre précédent, Statistique Canada avait préparé plusieurs projections parmi lesquelles on a retenu les projections A, B, C et D, ayant jugé qu'elles décrivaient le mieux les perspectives démographiques du Canada et de ses provinces. Les trois combinaisons suivantes présentent, toutefois, un certain intérêt. La première (projection E) part de l'hypothèse qu'il n'y aura aucune migration, tant au niveau international qu'au niveau interprovincial, avec une fécondité constante jusqu'en 2001. Ces projections hypothétiques sont indispensables aux démographes dans de nombreuses études théoriques; elles sont également utiles lors de la formulation de diverses politiques.

La seconde (projection F) a été produite selon les critères des Nations Unies et, comme dans la projection E, la fécondité y est maintenue constante au niveau observé au cours de la période de départ des projections. Cependant, on y suppose que les taux de migration et de mortalité seront du même ordre que ceux de la projection A (voir tableau 6.1). Le niveau spécifique de fécondité dans chaque province figure au tableau 7.1.

The third series, designated Projection G, is undertaken as a result of the consultations with users and outside experts. In essence, this series differs from the selected four Projections A, B, C and D in respect of future migration in particular at the provincial level, and assumes in some cases a net gain instead of loss, and in others, a smaller loss than that assumed previously. The interprovincial migration assumption used here denotes Assumption D described in Chapter 5 and the international migration involves a net gain of 100,000 persons a year (i.e., Assumption 2). Thus, under Projection G, the assumed net migration given in Table 7.1 will be positive for Quebec, Manitoba, and Prince Edward Island and will be considerably less for the other losing provinces than in the previous projections. The assumption implies for Saskatchewan a loss of only 5,900 a year compared to the amount between 8,400 to 21,700 in Table 5.6 for the selected four projections. Correspondingly, the gain will be at a reduced level for Ontario and British Columbia while Alberta is assumed to lose slightly.

According to Projection E which assumes zero migration, the population of Canada would amount to 25.4 million in 1986, i.e., 2.4 million less than Projection A (see Part III). This gap will widen to 5.9 million by 2001. The population under Projection F would amount to 27.1 million in 1986, and 32.6 million in 2001.

Projection G indicates for Quebec a population of 7.1 million in 1986 compared to 6.6 million under Projection B. Saskatchewan is projected to reach 979,000 which means 172,000 more than the expected population of 807,000 under Projection B. Likewise, the other losing provinces also are expected to have larger populations than anticipated in Projections A, B, C and D.

La troisième (projection G) est le résultat de consultations avec des utilisateurs et des experts. Pour l'essentiel, cette projection se distingue des quatre projections choisies (A, B, C et D) en ce qui concerne les prévisions de la migration, en particulier à l'échelle provinciale; elle suppose dans certains cas un gain migratoire au lieu d'une perte et, dans d'autres cas, une perte moins importante que celle qui était supposée dans les autres projections. L'hypothèse de migration interprovinciale utilisée ici rejoint celle de l'hypothèse D (voir chapitre 5) et l'hypothèse de migration internationale suppose un gain net de 100,000 personnes par an (voir hypothèse 2). C'est-à-dire que, selon la projection G, on prévoit un solde migratoire positif (voir tableau 7.1) au Québec, au Manitoba, et dans l'Île-du-Prince-Édouard et, pour les autres provinces (traditionnellement perdantes), une perte bien moindre que celle prévue dans les autres projections. Cette hypothèse suppose une perte de seulement 5,900 personnes par an pour la Saskatchewan, comparativement aux chiffres de 8,400 à 21,700 prévus selon les quatre autres projections (voir tableau 5.6). Par suite, les gains prévus pour l'Ontario et la Colombie-Britannique seront évidemment moins élevés et l'Alberta devrait connaître une légère perte.

Selon la projection E, qui suppose une absence de migration, la population canadienne devrait atteindre 25.4 millions d'habitants en 1986, soit 2.4 millions de moins que selon la projection A (voir partie III). La différence atteint 5.9 millions en 2001. Selon la projection F, le Canada compterait 27.1 millions d'habitants en 1986 et 32.6 millions en 2001.

Selon la projection G, le Québec devrait compter 7.1 millions d'habitants en 1986 contre 6.6 millions selon la projection B. La Saskatchewan devrait atteindre 979,000 habitants, ce qui représente 172,000 personnes de plus que le chiffre prévu par la projection B (807,000). De même les autres provinces perdantes devraient connaître des pertes bien moindres que celles qui sont prévues par les projections A, B, C et D.

## CHAPTER 8

### Availability of Unpublished Projections

The projections presented so far provide a wide choice for the general users. It is possible for some periods and/or for certain provinces that the future population will exceed or fall below the range indicated in this report. Annual migration had in the past fluctuated widely and changed direction as well and therefore, Statistics Canada does not recommend any one series to the users which is tantamount to undertaking **prediction** of the population.

Users may therefore be interested in other unpublished projections described in the Appendix. Besides, the projections programme as stated in Chapter 2 yields results by single years of age and sex for each year as of 1st June. The aforeseen projections are available in such detail, and Statistics Canada will be able to make available the additional age-sex particulars of published projections as well as the results of unpublished projections. Interested users may obtain these materials from Statistics Canada for the cost of computer time, zeroxing and clerical support. Request for these projections can be sent to Dr. K.S. Gnanasekaran, Population Estimates and Projections Division, Census Field, Statistics Canada, Ottawa K1A 0T7.

## CHAPITRE 8

### Autres projections disponibles

Les projections présentées jusqu'ici offrent un large éventail de possibilités aux utilisateurs. Il est possible que pour certaines périodes et (ou) pour certaines provinces, la population soit supérieure ou inférieure à celle prévue dans notre rapport. La migration annuelle a, dans le passé, fluctué considérablement; c'est pourquoi Statistique Canada n'a pas jugé bon de sélectionner une projection à des fins de **prédition**.

D'autres projections, dont la liste figure à l'appendice pourraient intéresser certains utilisateurs. En outre, le programme de projections dont il est question au chapitre 2 fournit les résultats des projections décrites dans ce rapport par année d'âge et pour chaque sexe au premier juin de chaque année. Ces résultats détaillés ainsi que les résultats des projections non publiées sont disponibles. On peut se les procurer en s'adressant à Statistique Canada, moyennant le paiement du temps d'ordinateur, des frais de photocopie et du travail de bureau. Les demandes doivent être envoyées à M. K.S. Gnanasekaran, Division des estimations et projections démographiques, Secteur du recensement, Statistique Canada, Ottawa K1A 0T7.

## CHAPTER 9

### Prospects for Population Growth: An Overview

The purpose of this final chapter is to highlight the main features that emerge from the analysis of Projections A and C regarding the growth, age structure and regional distribution of Canada's population. For Canada as a whole, Projection A embodies assumptions of relatively high fertility, namely 2.6 births per woman and a net gain of 100,000 immigrants each year, whereas Projection C implies a relatively low fertility of 1.8 births per woman and a net migration of 60,000. The fertility and migration assumptions incorporated in Projections A and C for the provinces are indicated in Tables 4.3 and 5.6 respectively.

## CHAPITRE 9

### Perspectives de croissance démographique: vue d'ensemble

Dans ce dernier chapitre nous allons tenter de faire ressortir les principales caractéristiques qui se dégagent de l'analyse des projections A et C en ce qui a trait à la croissance, la structure par âge et la répartition géographique de la population au Canada. En ce qui concerne le Canada tout entier, on constate que la projection A résulte d'une fécondité relativement forte, de l'ordre de 2.6 naissances par femme, et d'un apport net d'immigrants de 100,000 par année, tandis que la projection C prévoit une faible fécondité, de l'ordre de 1.8 naissance par femme, et une immigration nette de 60,000 personnes. Les tableaux 4.3 et 5.6 indiquent, respectivement, les hypothèses de fécondité et de migration des projections A et C, pour les provinces.

### Population Growth

During the period immediately following the Second World War, Canada's population expanded at the rate of approximately 3% per annum, but this rapid rate of growth came to an end late in the 1950's. Since then, the rate of growth fell to a low of 1.3% in 1972, the latest year for which actual rates can be calculated. The main factor in the slowdown of population growth is the decrease in the fertility level which brought the crude birth rate from its high of 28.2 births per 1,000 population in 1957 to 16.1 in 1972. A second factor contributing to the slower rate of population growth was net migration which fell from 6.8 per 1,000 population during 1951-1961 to 3.6 during 1961-1971.

What are the prospects for future growth? According to Projection A, after a few additional years of comparatively slow growth, Canada's population should enter a phase of increase (i.e., 1976-1981) during which the annual rate of increase may reach 2.0%, and then gradually subside to about 1.3% toward the end of the century. As the relatively large cohorts of women who were born during the comparatively high birth rate years of the late 'fifties and the early 'sixties enter their childbearing ages, the crude birth rate should increase from its current level of 16 per 1,000 to 23 around 1981, thereby resulting in the anticipated rise in population growth.

According to Projection C, the annual rate of population growth after a slight increase during 1976-1981, will gradually decline to about 0.5% toward the end of the century. Under the assumptions implied in this set of projections, the birth rate will rise slightly and then decrease to 12 per 1,000, while the death rate rises to 9 per 1,000 from its current level of 7 per 1,000. It should be noted that this slight increase

### Croissance démographique

Dans les années qui ont suivi la seconde guerre mondiale, la population canadienne s'est accrue à un rythme de 3 % par an environ, mais ce taux de croissance rapide s'est arrêté à la fin des années 50. Depuis, le taux de croissance a continué de diminuer pour atteindre 1.3 % en 1972, dernière année pour laquelle des estimations sont disponibles. Cette diminution de la croissance démographique s'explique principalement par la baisse du niveau de fécondité, qui a fait passer le taux brut de natalité de 28.2 pour mille en 1957 à 16.1 pour mille en 1972. Un second facteur a contribué au ralentissement de la croissance démographique; il s'agit de la migration nette qui est passée de 6.8 pour 1,000 entre 1951 et 1961 à 3.6 pour 1,000 entre 1961 et 1971.

Quelles sont donc les perspectives de croissance démographique? Selon la projection A, après quelques années encore de faible croissance, la population devrait entrer dans une phase d'expansion (1976-1981), au cours de laquelle le taux annuel d'accroissement pourrait atteindre 2.0 %, puis graduellement redescendre à 1.3 % environ vers l'an 2000. Lorsque les générations féminines relativement nombreuses nées à la fin des années 50 et au début des années 60 (années qui ont connu un taux de natalité relativement élevé) arriveront à l'âge de procréation, le taux brut de natalité devrait dépasser son niveau actuel de 16 pour 1,000 pour atteindre le chiffre de 23 pour 1,000 aux environs de 1981, entraînant ainsi l'augmentation de population prévue.

Selon la projection C le taux annuel de croissance démographique, après avoir augmenté légèrement entre 1976 et 1981, déclinera graduellement pour tomber à 0.5 % environ vers la fin du siècle. C'est ainsi que le taux brut de natalité pourrait augmenter légèrement pour ensuite descendre à 12 pour 1,000, tandis que le taux de mortalité pourrait passer de 7 pour 1,000 (taux actuel) à 9 pour 1,000. Il convient de noter que cette légère

in the death rate is expected to occur as a result of the aging of population postulated in Projection C.

According to these two sets of projections, in absolute numbers, Canada's population is expected to range from 25.4 to 27.8 million by 1986, and from 28.4 to 34.6 million by 2001. Details of growth patterns are portrayed in Chart 9.1.

No one can be certain about the levels of fertility and migration that will be attained in the future. Recent history provides ample evidence of unexpected swings in both fertility and migration levels to discourage analysts from making predictions of future population growth. However, qualified statements on the potentials of Canada's population growth may be made in light of the current demographic knowledge and the present set of projections. For example, it has been pointed in this report (Chapter 4) that a new baby boom of the post-war type is highly unlikely in the foreseeable future. The population is therefore likely to grow at a rate far less than that attained during the years till 1960.

However, there is no basis to expect that, as a result of the recent fertility decline, a cessation of population growth is imminent. Considerable potentials for growth are built into the age structure of the Canadian population, and this structure will cause population expansion even under low fertility and migration assumptions. It has been calculated that if fertility were to settle at the subreplacement level of 1.9 births per woman and if the gain through migration were to disappear completely, Canada's population would still continue to expand at about 1% per year to 1986 when it would reach 24.5 million, and 26.5 million by the turn of the century. Even with a fertility rate as low as 1.6 births per woman and net migration settled at 20,000 persons per year, Canada would have a population of 25.6 million by 2001.

The explanation for such a continuation of population growth is to be found in the age structure, since for many years to come the population will be comprised of a relatively large number of potential parents, pertaining to the cohorts born during the period when fertility was comparatively high. Consequently, the depressing effect of the current decline in fertility will be offset to some extent by the relatively large cohorts of women who will move into childbearing ages in the years to come.

#### Age Structure

Concomitant with the slowdown in population growth, the postulated fertility decline will cause the

augmentation du taux de mortalité serait le résultat du vieillissement important de la population que prévoit la projection C.

Selon ces deux projections, la population du Canada devrait se situer entre 25.4 et 27.8 millions d'habitants en 1986, et entre 28.4 et 34.6 millions en 2001. Le graphique 9.1 montre plus en détail l'évolution prévue.

Personne ne peut dire avec certitude ce que seront les niveaux de fécondité et de migration dans les années à venir. L'évolution récente fournit à l'analyste assez d'exemples de modifications inattendues dans les niveaux de fécondité et de migration pour le décourager de faire toute prédiction quant à la croissance démographique future. Toutefois, à partir des connaissances actuelles en démographie et des projections présentées ici, on peut faire un certain nombre de prévisions raisonnables sur les possibilités de croissance de la population canadienne. Par exemple, on a avancé dans la présente étude (voir chapitre 4) qu'il était peu probable qu'une nouvelle explosion démographique, de l'importance de celle d'après-guerre, ait lieu dans un avenir prévisible. La population devrait plutôt s'accroître à un rythme plus modéré que celui des années d'après-guerre (jusqu'à 1960).

Par ailleurs, il n'y a aucune raison de croire qu'à la suite de la baisse récente de la fécondité la croissance démographique risque de s'arrêter très prochainement. La composition par âge de la population canadienne offre des possibilités considérables de croissance pouvant lui assurer une expansion démographique même dans des hypothèses de migration et de fécondité faibles. On a calculé que, si la fécondité se stabilisait au niveau de 1.9 naissance par femme (soit en-dessous du niveau de remplacement) et s'il n'y avait aucune augmentation de population due aux migrations, la population canadienne continuerait tout de même à s'accroître au rythme d'environ 1 % par an jusqu'à 1986; elle atteindrait alors les 24.5 millions d'habitants, puis 26.5 millions vers l'an 2000. Même avec un taux de fécondité aussi bas que 1.6 naissance par femme et un soldé migratoire de 20,000 personnes par an, le Canada aurait une population de 25.6 millions d'habitants en 2001.

Le fait que la population continuera malgré tout à s'accroître s'explique par la structure des âges: en effet, pour de nombreuses années à venir, la population sera constituée d'un nombre relativement important de parents "en puissance" appartenant aux générations nées à une époque de fécondité relativement élevée. En conséquence, l'effet négatif de l'actuelle baisse de la fécondité sera compensé, dans une certaine mesure, par le nombre relativement important de femmes qui atteindront l'âge de la procréation dans les années à venir.

#### Structure par âge

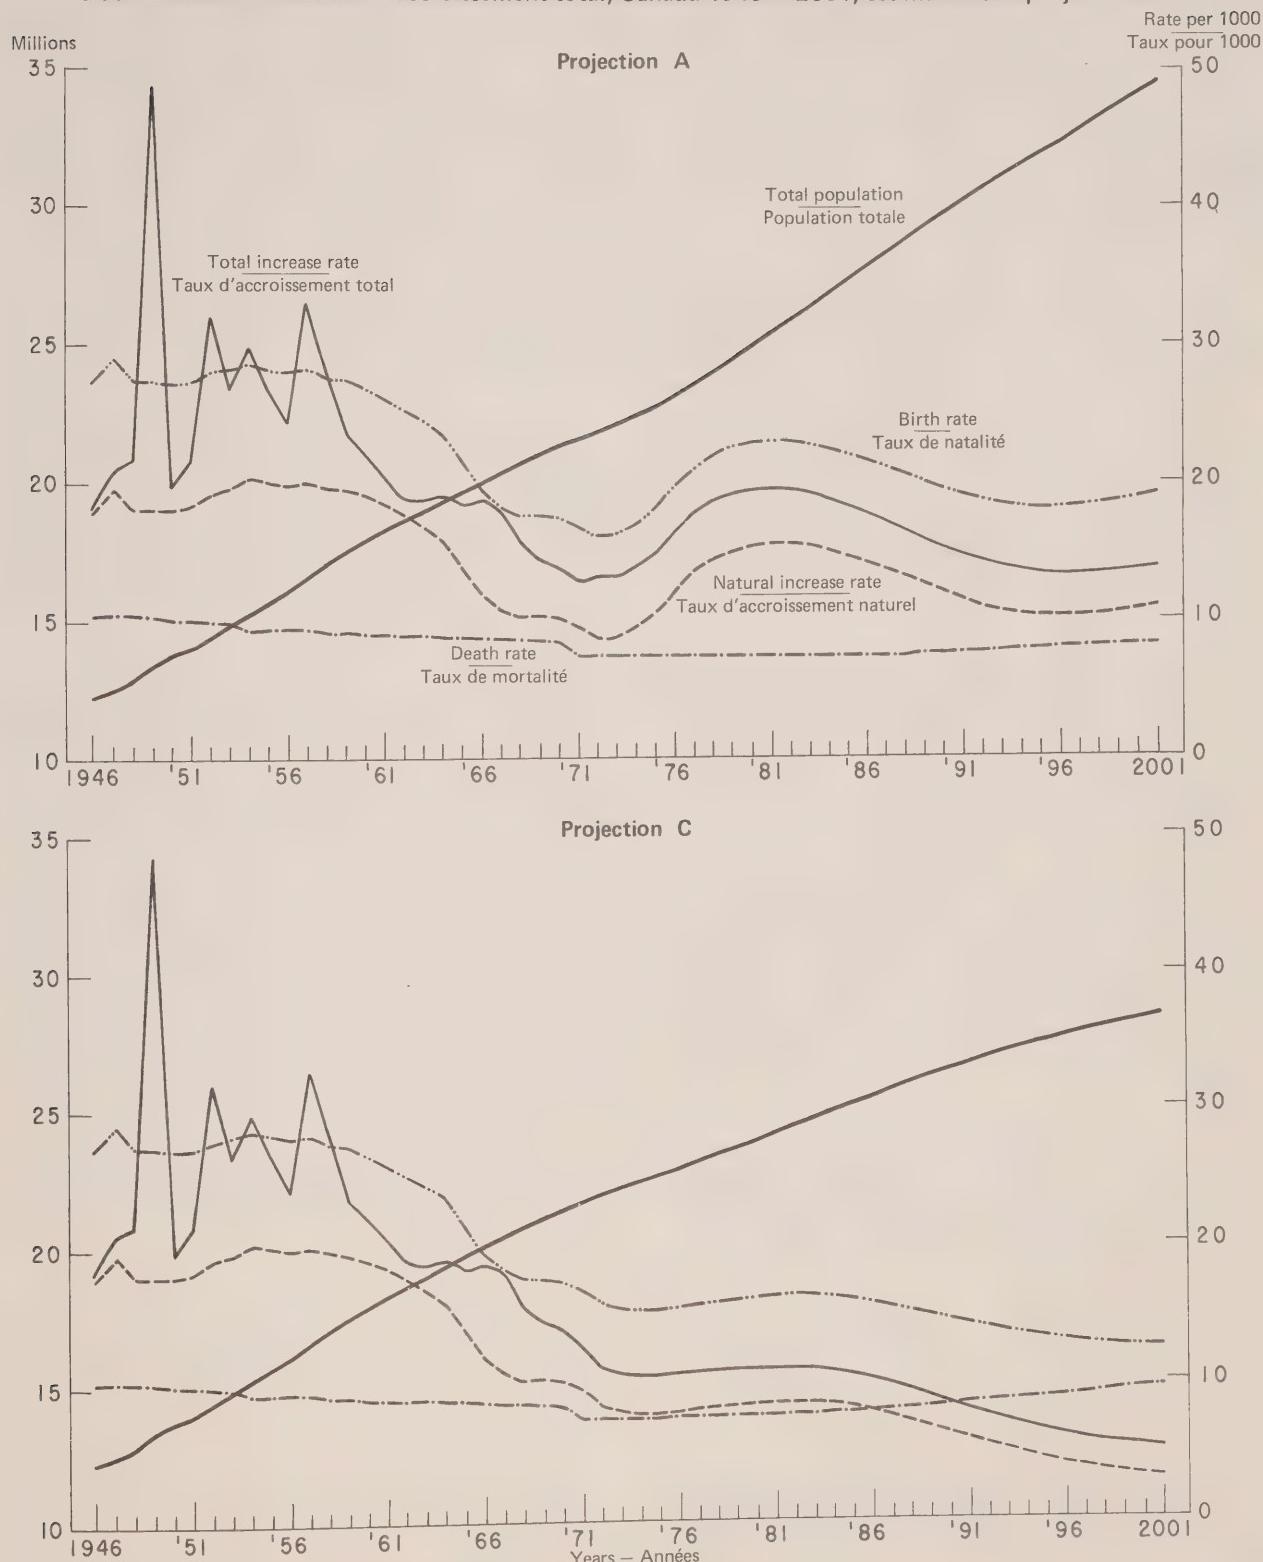

En même temps qu'un ralentissement de la croissance démographique, la baisse prévue de la fécondité

aging of Canada's population. If fertility declines to the level implied in Projection C, the mean age of population will increase gradually from 31 to 37 years toward the end of the century. During the same period, the proportion under age 20 will drop from 39% in 1971 to 27%, and the proportion over age 65 will increase from 8% to 12%. As a result of this upward shift in the age structure, there will be a steady decline in the child-dependency ratio and an increase in the old age dependency ratio. A younger age structure, as depicted in Charts 9.2 and 9.3, is implied in the relatively high fertility assumption.

Turning to the absolute and relative increase in particular age groups, the analysis of projections gives rise to the following observations, which are supported by the data in Table 9.1 and Chart 9.4.

The group under age 20, after having experienced a period of rapid increase, is expected to abate considerably or even to decrease in the years to come. Thus under the relatively high fertility assumption its size is expected to increase only by 11% over the period 1971-1986 as against 33% during 1956-1971. Under the low fertility assumption, its size will decline by 13%.

As for the age group more directly associated with school attendance and professional training, i.e. ages 6 through 19, its number is expected to diminish from 6.3 million in 1971 to 5.9 and 5.1 million in 1986, that is a decrease of 6% and 19%, under high and low fertility assumptions respectively.

The population in working and childbearing ages, 20 to 44 years, is expected to have a record increase in the range of 46% to 51% up to 1986, compared to an increase of only 29% in the last fifteen years. It is this increase in the number of potential parents which gave rise to the assumptions made above that the birth rate should increase even if fertility remains at its current low level.

The 45-64 year age group is made up of the cohorts who were born during the period of lower fertility levels attained in the twenties and the thirties, and consequently this age category is comparatively small.

The old age segment of the population, i.e., those aged 65 or older, is expected to grow from its 1971 level of 1.7 million to approximately 2.6 million in 1986 or an increase of 48%.

Of all the age groups reviewed above, the group under 20 is subject to large projection error, since its size will be determined largely by the prospective fertility which is most difficult to predict. As to the age groups over 20, with the exception of the effect of

provoquera un vieillissement de la population canadienne. Si la fécondité tombe au niveau prévu par la projection C, l'âge moyen de la population actuellement de 31 ans augmentera graduellement pour atteindre 37 ans vers la fin du siècle. Au cours de la même période, la proportion des jeunes de moins de 20 ans passera de 39 % en 1971 à 27 % et la proportion des plus de 65 ans passera de 8 % à 12 %. À cause de ce vieillissement de la population, on assistera à une baisse régulière de la proportion des enfants à charge et à une augmentation de la proportion de personnes âgées à charge. Par contre une hypothèse de fécondité relativement élevée entraînerait une population plus jeune, comme on peut le voir aux graphiques 9.2 et 9.3.

En ce qui concerne l'accroissement de certains groupes d'âges, l'analyse des résultats suggère les remarques suivantes, illustrées par les données du tableau 9.1 et du graphique 9.4.

Le groupe des moins de 20 ans, après une période de rapide expansion devrait connaître un ralentissement considérable, voire même une baisse dans les années à venir. Ainsi, si l'on retient l'hypothèse d'une fécondité relativement élevée, ce groupe devrait augmenter de seulement 11 % de 1971 à 1986 contre 33 % entre 1956 et 1971. Et selon l'hypothèse de faible fécondité, il devrait diminuer de 13 %.

Quant au groupe le plus directement touché par la fréquentation scolaire et par la formation professionnelle (c'est-à-dire le groupe des 6 à 19 ans), il devrait passer de 6.3 millions en 1971 à 5.9 et 5.1 millions en 1986, soit des baisses de 6% et 19%, selon qu'on retient respectivement les hypothèses de forte ou de faible fécondité.

Le groupe des 20-44 ans, soit la population en âge de travailler et de procréer, devrait connaître une augmentation record de l'ordre de 46 % à 51 % jusqu'en 1986, comparativement à seulement 29 % au cours des 15 dernières années. C'est cet accroissement du nombre de parents "potentiels" qui a donné lieu à l'hypothèse que le taux de natalité augmentera même si le niveau de fécondité reste le même qu'actuellement.

Le groupe des 45 à 64 ans, constitué des générations nées au cours de la période de faible fécondité des années 20 et 30 est en conséquence relativement peu nombreux.

Le segment de la population constitué par les personnes âgées (65 ans et plus) pourrait passer de 1.7 million en 1971 à environ 2.6 millions en 1986, soit une augmentation de 48 %.

De tous les groupes d'âges considérés ci-dessus, c'est le groupe des moins de 20 ans qui est sujet aux erreurs les plus importantes car son nombre dépend en grande partie de la fécondité à venir, très difficile à prévoir. Quant au groupe des plus de 20 ans, si on exclut les effets de la

net migration, their future size is determined by mortality, which has a relatively minor effect for the population under age 65. Mortality projections, including those for persons aged 65 or over, are unlikely to generate great error in the projected figures of these adult and old age groups.

In short, future population movements are likely to be dominated by an upward shift in the age structure, an over-all aging of population, a slow increase or even numerical decline of groups in the formative ages, and a sizable increase in the number of elderly people.

#### Regional Distribution

Changes in fertility and migration by provinces, if they occur in the manner implied in Projections A and C, will entail considerable shifts in the provincial and regional distribution of population. As is shown in Table 9.2, some provinces are likely to experience a high tempo of population growth, others will expand at a low to moderate rate and still others may encounter a population decline.

The provinces of British Columbia, Ontario and Alberta stand the prospects of a comparatively high rate of population growth. The increase over the 1971-1986 period is expected to range from 42% to

migration, son importance future ne dépend que de la mortalité, facteur relativement peu important pour les moins de 65 ans. La projection de la mortalité (en incluant les 65 ans et plus) ne devrait pas entraîner d'erreurs très importantes dans les effectifs d'adultes et de personnes âgées.

En bref, l'évolution démographique à venir pourrait être caractérisée par un vieillissement général de la population, un faible accroissement ou même une diminution des groupes d'âge scolaire et un accroissement sans précédent du nombre des personnes âgées.

#### Répartition géographique

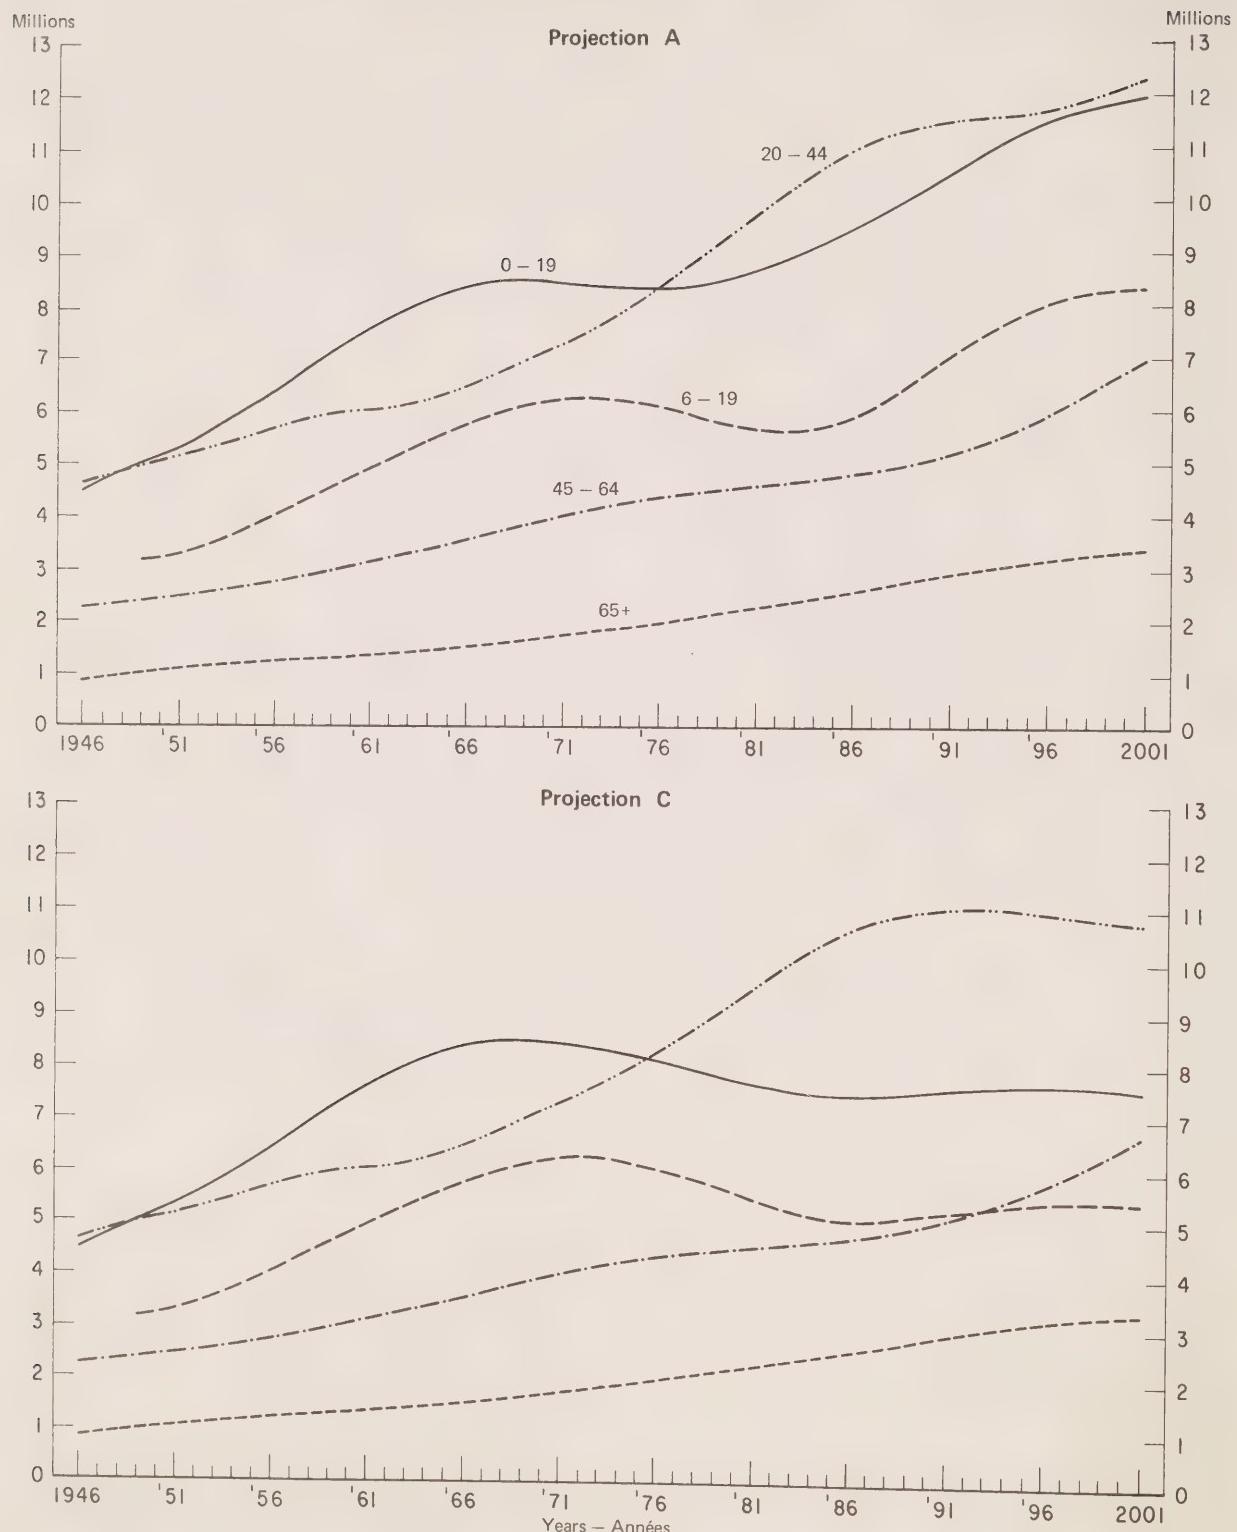

L'évolution de la fécondité et de la migration dans les provinces, si elle se produit telle que prévue selon les projections A et C, entraînera des changements importants dans la répartition de la population par province. Comme le montre le tableau 9.2, certaines provinces pourraient connaître une forte croissance démographique tandis que d'autres auraient une croissance modérée ou faible; d'autres encore pourraient même faire face à une réduction de leur population.

Les provinces de la Colombie-Britannique, de l'Ontario et de l'Alberta peuvent s'attendre à une croissance démographique relativement forte: leur taux de croissance entre 1971 et 1986 pourrait être de l'ordre de

**Source:** Same as Table 9.1. — Les mêmes que celles du tableau 9.1.

55% for British Columbia, from 27% to 42% for Ontario, and from 27% to 40% for Alberta.

42 % à 55 % pour la Colombie-Britannique, 27 % à 42 % pour l'Ontario et 27 % à 40 % pour l'Alberta.

The three Prairie provinces taken together are projected to experience a low to moderate rate of increase of 8% to 17%. Similar rates are projected for the Atlantic provinces. There are, however, significant intraregional variations in the rate of population growth as shown in Table 9.2. The case in point is the province of Alberta examined above, with its relatively high rate of increase.

Dans l'ensemble, les trois provinces des Prairies devraient connaître un taux de croissance allant de faible à modéré, soit de 8 % à 17 %. On prévoit des taux du même ordre pour les provinces de l'Atlantique. Cependant, comme on le constate au tableau 9.2, il existe des variations importantes d'une province à l'autre. L'Alberta, dont on a parlé plus haut, en est un exemple avec son taux de croissance relativement élevé.

A rather different prospect of population growth is faced by Saskatchewan. This province has experienced recurrent losses in population through out-migration. If the current trends in migration continue, its population may diminish, according to these projections, from 926,000 in 1971 to a range of 758,000 to 776,000 by 1986.<sup>1</sup> This picture of the

La Saskatchewan fait face à des perspectives de croissance bien différentes. Cette province a perdu régulièrement une partie de sa population à cause de l'émigration. Si la tendance actuelle dans les migrations se poursuit, sa population pourrait diminuer, et passer de 926,000 habitants en 1971 à 776,000 et même à 758,000 en 1986<sup>1</sup> selon la projection en cause. Si la Saskatchewan

<sup>1</sup>If out-migration is less, as under Projection D, the population of Saskatchewan would lie between 758,000 and 905,000 in 1986 (see Chapter 6 and Table 6.2).

<sup>1</sup> Si l'émigration était moindre, comme le suppose la projection D, la population de la Saskatchewan pourrait, en 1986, atteindre 905,000 habitants (voir chapitre 6 et tableau 6.2).

demographic future of Saskatchewan may not materialize if the outflow of its inhabitants is less. A more balanced relation between Saskatchewan's in- and out-migration would certainly change the demographic outlook. Indeed, it should be kept in mind that its potential for growth through the renewal process of births and deaths is above the national average level. In fact, of all major provinces, Saskatchewan has the highest fertility rate at 2.71 births per woman in 1971 as against 2.19 for Canada.

Quebec's demographic prospects require also a special mention. According to the projections reviewed here, its population will continue to expand, although at a comparatively slow rate: a total increase between 6% to 13% from 1971 to 1986. However, a closer analysis of the underlying growth factors suggest a slower long-term growth potential of its population. In recent years, Quebec's out-migration has consistently outweighed its in-migration. Quebec's fertility, on the other hand, has fallen from its previous level of the highest in Canada to 1.7 births per woman (1972) which is considerably below the replacement level. Although a reversal in this trend should not be ruled out, and some projections included in this report actually make provisions for a rising fertility, the fact that for several years now Quebec has had the lowest fertility in Canada may suggest that low fertility in Quebec could continue in the future. For many years to come, Quebec's population growth (as is the case for Canada as a whole), will reflect a favorable age structure. In the long run, however, unless the situation with respect to fertility and/or migration is changed, Quebec can expect to experience a considerable reduction in its population growth.

As stated in the introductory chapter of this report, these projections do not purport to predict the future population; rather, they are conditional upon the attainment of the implied assumptions regarding components of population change, namely fertility and migration, and to a lesser degree, mortality. It should be emphasized that the anticipated decline in the population growth of Saskatchewan and, in the longer run, Quebec, will occur only if the assumed trends for these provinces come to prevail in the future.

Because of the current and anticipated inter-provincial differentials in the rates of population growth, considerable shifts in the distribution of Canada's population among the provinces and regions will take place in the future, as revealed by Table 9.3 and Chart 9.5. If the trend implied in projection A actually materializes, Ontario will represent 39% and 42% of Canada's population by 1986 and 2001 respectively as compared to 36% in 1971. British Columbia will also notably increase its relative weight. All other regions and provinces, with the possible exception of Alberta, may see their relative weight

arrivait à établir un équilibre entre les entrées et les sorties, sa situation démographique en serait considérablement modifiée. Il faut en effet se rappeler que, grâce au mouvement naturel des naissances et des décès, son potentiel de croissance se situe au-dessus de la moyenne nationale. En fait, de toutes les grandes provinces, la Saskatchewan est celle qui a la fécondité la plus élevée, soit 2.71 naissances par femme en 1971 contre 2.19 pour le Canada.

L'évolution démographique du Québec mérite une attention particulière. Selon les projections présentées dans notre étude, sa population continuera d'augmenter bien qu'à un rythme relativement lent; soit un accroissement de 6 % à 13 % entre 1971 et 1986. Toutefois, une analyse plus poussée des facteurs de croissance laisse présager un rythme de croissance plus lent à long terme. Au cours des dernières années au Québec, les sorties ont été considérablement plus importantes que les entrées. D'autre part, la fécondité, auparavant la plus élevée du Canada, est tombée à 1.7 naissance par femme en 1972. Bien qu'un renversement de cette tendance ne soit pas impossible (certaines projections dans ce rapport prévoient une augmentation de la fécondité), le fait que le Québec, depuis plusieurs années déjà, ait le niveau de fécondité le plus faible du Canada peut indiquer que cette faible fécondité se maintiendra dans les années à venir. Pendant de nombreuses années encore, la croissance démographique du Québec, comme c'est le cas pour l'ensemble du Canada, profitera des effets favorables de la structure par âge. À long terme pourtant, à moins que la situation de la fécondité et/ou de la migration ne se modifie, le Québec doit s'attendre à une diminution considérable de sa croissance démographique.

Comme nous l'avons dit dans l'introduction, les projections présentées ici ne prétendent pas faire de prédictions quant à la population future du Canada; elles dépendent en fait de la façon dont se vérifieront les hypothèses relatives aux facteurs de l'évolution démographique: la fécondité et la migration et, dans une moindre mesure, la mortalité. Il convient d'insister sur le fait que les diminutions de croissance démographique prévues pour la Saskatchewan et, à plus long terme, pour le Québec ne se matérialiseront que si les tendances démographiques prévues se réalisent dans les années à venir.

En raison des différences présentes et futures entre les provinces dans les taux de croissance, il se produira des changements importants dans la répartition de la population canadienne entre les provinces et les régions, comme l'illustrent le tableau 9.3 et le graphique 9.5. Si les tendances prévues par la projection A se vérifient, l'Ontario contiendra 39 % et 42 % de la population canadienne respectivement en 1986 et en 2001, comparativement à 36 % en 1971. La Colombie-Britannique augmentera elle aussi notablement sa part relative. Toutes les autres provinces et régions, à l'exception peut-être de l'Alberta, pourraient voir diminuer leurs proportions de la

diminish. The population of Quebec as a percentage of Canada's population is expected to decrease from 28% in 1971 to 25% in 1986 and to 22% in 2001.

population totale. Par exemple, la part du Québec dans l'ensemble du pays devrait passer de 28 % en 1971 à 25 % en 1986 et 22 % en 2001.
